The disaster last week at Oppau in the Rhine Province has recalled attention to one of the terrible episodes of the war, for whatever was the actual source of the explosion, the Ludwigshafen Aniline Works were notorious as one of the principal manufactories of poison gases. During actual hostilities, chemical warfare is an engrossing occupation to a large proportion both of attackers and defenders, as well as a painful concern to the whole civilian community. In times of peace it naturally tends to lose interest except for small groups of strategists preparing for the next campaign, chemists interested in toxicology, humanitarians who are out to prevent any campaign at all, and doctors whose duty it is to stand by in any event to anticipate and prevent bodily suffering and disability. The problem is a baffling one. It would be logically convenient to limit a discussion on chemical warfare to the view-point of any one of these groups, but the borderland is apt to be crossed. This was notably the case with the protest made at Edinburgh by the President of the British Association against the diversion of the brains employed in the promotion of his science to the perfecting of means for destroying mankind. Sir Edward Thorpe brushed on one side the sophistical talk about the painlessness or temporary effect of poison gas, and made a dignified appeal to the Association to set its face against the continued degradation of science in augmenting the horrors of war, and to use its influence in resisting a course of action which is the very negation of the civilisation which natural knowledge has done so much to build up. It is surely idle to dally with the notion that any effective form of chemical warfare can be genial or humane. The offensive agents devised in the laboratory are useful from the military point of view in proportion to their power to maim, torture, and kill the enemy, and their moral effect on him is in proportion to the horrors of their physical effect. Although it seems plainly wrong-headed to refuse to recognise that the objections which should reasonably prevent civilised nations from using phosgene or mustard gas are equally cogent against the employment of high explosive shell or any other recognised agent of destruction, allowance must be made for the psychological difference between using what you have and trying to devise something "better." As those engaged in the study of natural science will be the first to admit, nothing can remain as it is; if there is no progress decay inevitably follows. The implications involved in the continued prosecution of chemical warfare are of an order which may properly be described as fundamental. It is a question not only of the progress of chemical research but of the continuance of civilisation. It should be recognised that what Sir Edward Thorpe protests against is not a possibility but a reality. There is in existence a War Office organisation for the prosecution of research in the offensive and defensive aspects of chemical warfare with which are associated some 50 or 60 chemists, physicists, physiologists, and medical men. Their experimental ground near Salisbury is still in being. Whether anything of offensive military value is being discovered is naturally not known; progress along defensive lines is obviously as impossible as to discover the cure for an unknown disease. The scientific members of this Chemical Warfare Committee may find food for reflection in what Sir Edward Thorpe has said.

THE SPREAD OF HUMAN COCCIDIOSIS.

In 1915 H. M. Woodcock announced the discovery of a human coccidium in a man who had been invalided from Gallipoli. The discovery was quickly confirmed by G. C. Low and C. M. Wenyon, while the latter demonstrated that the coccidium belonged to the genus *Isospora*. Since that time a number of cases have been described from different parts of the world, and having encountered a case in the Philippines, Dr. F. G. Haughwout reviews[1] the situation and shows that practically all the cases can be traced either directly or indirectly to the Eastern Mediterranean area and that this coccidium has now circumnavigated the globe. Such is the influence of the war in spreading infections. Infections in men who had been in the Eastern Mediterranean war area have been recorded in England, Italy, Egypt, Salonika, and America, while in India they have been noted in men returning from Mesopotamia. In all these cases it appears that the infection was contracted in Turkish territory. In America, however, C. A. Kofoid discovered infections not only in men who had been abroad but also in others, so that it would seem that the infection may have been established in this country. A case recorded by F. Noc from West Africa was in a man who had been a prisoner of war in Germany, and the writer believes that the infection may have been contracted from other prisoners from the Eastern Mediterranean.

THE LANCET.

LONDON: SATURDAY, OCTOBER 1, 1921.

The Health Committee of the League of Nations.

The Assembly of the League of Nations has now recast the proposals for the new Health Organisation of the League to meet political difficulties which, for the time being, prevent the accomplishment of the procedure which was settled at the first Assembly in December of last year.[1] In order to promote international measures for the improvement of public health, which is required of it by the Covenant, the League then decided to have an organisation which included a health council, with a small paid secretarial staff at Geneva, together with a consultative body on which as many national public health services as possible were represented. The latter body, which exists already in the Office International d'Hygiène Publique, was to be brought under the direction of the League, and practically was to nominate the Health Council, which in turn would appoint the Secretariat. The machinery now to be substituted, in consequence of the objections made by the United States to participating in an official organ of the League of Nations, consists of a Health Committee nominated directly by the Council of the League, and a small secretariat under a medical director, directly appointed by the secretary general of the League. To this post Dr. L. Rajchman, of Warsaw, has been appointed, and the personnel of the Committee, wide nationally as well as professionally, was given in our issue of Sept. 17th. The essential advisory body, which will bring the League into touch with official public health opinion in all countries, can fortunately still be found in the Office International d'Hygiène Publique, though it remains for the present, at the wish of the U.S.A., outside the League. The Office, while remaining autonomous with its present statutes and organisation under the Rome Convention of 1907, has signified its readiness to aid the League and will be systematically consulted by the Health Committee. The two bodies already have sufficient membership in common to keep them in close touch with each other.

The main functions which the League desires its Health Organisation to fulfil are not materially changed. They are stated as follows in the resolutions which have just been adopted by the Assembly, and are to be carried out in coöperation with the Office International d'Hygiène Publique:—

(*a*) To advise the League of Nations in matters affecting health.

(*b*) To bring administrative health authorities in different countries into closer relationship with each other.

(*c*) To organise means of more rapid interchange of information on matters where immediate precautions against disease may be required (e.g., epidemics), and to simplify methods for acting rapidly on such information where it affects more than one country.

(*d*) To promote the conclusion of international agreements necessary for administrative action in matters of health, and their revision when circumstances require, and to collect information as to action taken to give effect to such agreements.

(*e*) In regard to measures for the protection of the worker against sickness, disease, and injury arising out of his employment, which fall within the province of the International Labour Organisation, the Health Organisation will coöperate with, and assist, the Labour Organisation, it being understood that the Labour Organisation will, on its side, act in consultation with the Health Organisation in regard to all health matters.

(*f*) To confer and coöperate with international Red Cross Societies and other similar societies.

(*g*) To advise, when requested, other voluntary organisations in health matters of international concern.

(*h*) To organise missions in connexion with matters of health with the concurrence of the countries affected.

The chief service which the League of Nations can render to public medicine, within the limits of the small budget allotted for the purpose, consists in facilitating combined action in matters where many Governments are interested but where no one Government can be expected to act by itself. The immediate questions with which the Health Committee of the League has already made a beginning seem to afford good examples of practical and useful work of this nature. The Committee considered it essential to effective work that the Epidemics Commission of the League of Nations should be amalgamated with the Health Organisation of the League, and this view has been accepted. The results achieved by that Commission have been of great value in preventing the spread of typhus and other epidemic diseases from Russia to Western Europe, and all information available regarding the epidemic situation in Russia at the present time points to the necessity of fully maintaining these measures and extending them wherever necessary to border States other than Poland. This is particularly requisite in consequence of the grave risks which may be run by the spread of infection of cholera from the parts of Russia now affected by famine. First-hand information is now to be secured by a visit to Russia on the part of representatives of the Commission. The Health Committee felt also that a service of epidemiological intelligence and public health statistics will form a most important part of its work, and it was decided in consequence to start an immediate inquiry to determine the best methods for collection and distribution of such intelligence. As a result of the International Opium Convention the Health Committee has accepted a reference from the Council asking it to undertake an inquiry in certain countries in which the use of morphine, cocaine, and other dangerous drugs is said to be excessive as well as in certain others in which its use is at present more probably limited to medicinal and other legitimate purposes, with a view to obtaining information concerning the average quantities that might be regarded as reasonably needed for medical use in different classes of population.

◆

Publication and Progress.

The enormous increase in the cost of printing has put a serious obstacle in the way of the advancement of learning. From the point of view of the humanities Sir Charles Oman had a good deal to say about it at the recent meeting of the Library Association in Manchester, and on the scientific side Mr. W. B. Brierley, of Rothamsted, crystallises in *Nature* what everyone in contact with research work has been feeling for some time past. Serious work for the improvement of knowledge must be completed by publication of some sort unless its purpose is to be enthusiasts lay most stress on the building up of good sound teeth, which will resist decay, by means of more careful attention to the dietary of childhood and adolescence. The committee appointed is a representative one, and we do not doubt that its findings will give a great and much needed stimulus to the campaign against this extremely important cause of ill-health and physical disability. Sanitary reformers, who know the far-reaching effects of dental decay and oral sepsis, have been anxiously waiting for a lead.

OSWALD SCHMIEDEBERG.

There is something pathetic in the fact that Oswald Schmiedeberg should have outlived the post of professor of pathology in the German University of Strassburg, which he held during the whole period of German occupation from 1872 till 1918. Born in Kurland in Russia in 1838, he died after a short illness on July 12th of this year at Baden Baden, where he had gone to live near his friend Naunyn. Even the German medical papers seem to have lost him in his retirement, for they do not report his death till September. He was a prolific writer himself, and the articles inspired by him would be difficult to count. He is known for his theory that alcohol is in no sense a stimulant of the central nervous system, but that it depresses from the beginning, dulling the highest centres first and the medullary centres last of all, the so-called stimulant effects being merely due to depression of the inhibitory centres. He was less happy in his advocacy of organic iron compounds. His well-known Arzneimittellehre, translated into English in 1887 as "Elements of Pharmacology," has served as a model for text-books on pharmacology. Schmiedeberg's life was bound up in his institute and his scientific work, and he was one of a group of German scientific workers who have formed a school round them by attracting students from all parts of the world. Cushny and Stockman studied under him in Strassburg. While not coming into the class of Pasteur, Ehrlich, and Koch, he was certainly one of the great pioneers of experimental pharmacology.

MEDICAL EVIDENCE FOR THE DEFENCE.

Sir Edward Marshall-Hall, K.C., in addressing the jury on behalf of a medical man[1] charged with administering drugs to women for an illegal purpose, made the interesting suggestion that the Medical Defence Union should organise a rota of medical men who would be prepared to give evidence on behalf of an accused person, or to give the advantage of their knowledge to the court. In saying this Sir Edward Marshall-Hall appears to have had in his mind the power of the Crown to assemble medical witnesses against a prisoner, and the inability in many cases of a prisoner to obtain expert evidence on his behalf through lack of means. He referred, no doubt, to all classes of accused persons and not only to medical men, who generally can obtain such evidence owing to their professional position. He meant also, we presume, that such evidence should be given gratuitously. From a medical point of view the suggestion is rather attractive. It is certainly a hardship that a man's liberty should be placed in danger for lack of a medical witness able to criticise the medical evidence given for the prosecution and to put the medical aspect of the prisoner's case in a more favourable light. The giving of such aid as is indicated might, in conceivable cases, be a work of the truest charity. Whether the innovation would be generally practicable and welcomed by all parties is a slightly different matter. Sir Edward Marshall-Hall has had very great experience, perhaps greater than any other present member of the Bar, in the defence of difficult criminal cases. One would like to ask him whether, apart from the particular case that he was fighting, and the needs of a particular client, he would wish to see the system instituted which he has suggested, and considers that it would prove workable in practice. Probably in many instances the suggested medical witnesses would agree with the evidence given by the witnesses on behalf of the Crown. Further questions suggest themselves for consideration. Would the fact that such witnesses were not called prejudice the defence, and would the jury be unduly influenced against a prisoner by their absence? Would they be regarded as putting themselves forward as professional witnesses for the defence, and would the weight of their evidence be lessened thereby? It would be useful to know whether other counsel of experience in criminal courts agree with Sir Edward Marshall-Hall.

SMALL-POX AND VACCINATION.

At the present time a considerable proportion of the English people are under the impression that small-pox is no longer to be looked upon as a formidable disease, and that they may safely ignore the Vaccination Acts. The present generation has had no object-lesson of epidemic small-pox, and consequently has no fear of the disease; the belief appears to be widely prevalent that small-pox is to be reckoned among the diseases which have practically become extinct in England and Wales in consequence of the high standard of sanitation now exacted by local health authorities. The former ravages of variola in this country in pre-vaccination days are not realised—the heavy mortality of children, the blindness among many of the survivors, the facial disfiguration, along with other sequelæ. Nor does it appear to be generally recognised that small-pox is continually manifesting itself in epidemic form in one or another part of the world, that the infection is constantly being carried by shipping from one continent to another, and that England, from its geographical position and its world-wide commerce, is peculiarly exposed to the risks of imported small-pox.

To dispel this ignorance and remove the misapprehensions which have arisen in the public mind is a course that is obviously necessary in the interests of public health. Something could be done to improve the present situation if the public were put in possession of trustworthy information concerning small-pox and vaccination. Probably it has been with this object in view that the Medical Department of the Ministry of Health has prepared for circulation a small pamphlet[1] on this subject, written in plain and concise language, and summarising the main facts concerning small-pox and its only prophylactic—vaccination. An account is given of the behaviour of the disease in pre-vaccination days, and a description of how inoculation was tried and found wanting, how vaccinia was introduced by Jenner, and what were the early experiences of it in this country. There is also given a brief résumé of the present administrative arrangements for vaccination in England and Wales, and a short description of the Government Calf Lymph Establishment. Perhaps the most interesting section is that which deals with the present state of vaccination in the population of this country. In this connexion our readers may remember that the Royal Commission on Vaccination, in its final report presented in 1896, recommended that exemption should be granted to those parents who honestly believed that vaccination would be injurious to the health of their children. The Vaccination Act of 1898 therefore contained a provision allowing exemption in cases in which the applicant satisfied the magistrates that his conscientious objection was a genuine one. The Act of 1898 also instituted domiciliary instead of stational vaccination, and made obligatory the use of Government glycerinated calf lymph by public vaccinators. These concessions resulted in a better observance of the vaccination laws, and the percentage of vaccinations to births,

Health Insurance and the State.

THE State itself has a big responsibility in the matter—we begin where we left off a week ago. The mechanism set up under the National Insurance Acts makes it possible to carry out a concerted scheme for safeguarding the national health when the human elements in the scheme shall have all found appropriate place. To scrap this mechanism, for the State to withdraw its contribution and its directing influence, is now being seen for the calamity that it would be. It was solely the intervention of a department of State in the region of sickness insurance that opened up the sphere of public health and preventive medicine to the general practitioner. With the institution of a panel service the skill and experience of the family practitioner, unique in so many ways, was enlisted in a health service, no less truly a public health service because it bore a misleading name until it was united with the more technical Public Health Department of the Local Government Board to become the Ministry of Health. It is inconceivable that the General Practitioner Services of this Ministry should now be sacrificed in the interests of a so-called economy. The department, still in its infancy, will, we fancy, manifest the vitality of the young kitten which refuses to be drowned; if only for the reason that it is essential to the building-up of an ideal health service which has yet to include the provision of nursing, dentistry, hospital clinics, and pathological laboratories, all of which were foreshadowed when the first Insurance Act became law. Despite the urgent need of real economy, the responsibility of the State for the health of the citizen is no less than it was.

Much has been said in public and private during the week on the merits and demerits of the various human agencies which drive the mechanism. There is a reciprocal consensus of opinion that much improvement is possible. But two things stand out as noteworthy. One is the testimony of the chief organ of the approved societies that to discontinue medical benefit would be an unspeakable calamity. Our information, so writes the *National Insurance Gazette* for Sept. 17th, is to the effect that in most parts of the country medical benefit is a success. Conviction of this fact having been brought home to the critical member of the party, the value of medical benefit in the insurance scheme may fairly be considered as established for all practical purposes. The second item worthy of note is that on Sept. 23rd, at their annual conference, the group of friendly societies turned down a resolution to urge a national medical service upon the Ministry of Health, after hearing Dr. J. F. GORDON DILL set forth by invitation the provident scheme for extending hospital and additional services. All this is in harmony with the resolution to be laid before the coming Conference of Panel Committees, that the measure of success which has attended the experiment of providing medical benefit under the National Health Insurance Acts system has been sufficient to justify the medical profession in uniting to ensure the continuance and improvement of this system.

THE LANCET of January 1st, 1921.

THE Manager will be obliged to readers who have not any further use for their copy of THE LANCET of the above date if they will kindly return it to him at 1, Bedford-street, Strand, W.C. 2. The postage on the number is three halfpence. He will be pleased to pay for those returned.

Annotations.

"Ne quid nimis."

PSYCHOTHERAPY IN RELATION TO MEDICINE.

THE future of psychotherapy and the place that it will eventually occupy in medicine affords an interesting subject for speculation. At present in its infancy, it has been brought to the fore, largely as the result of the numbers of cases of functional nervous disorders directly or indirectly attributable to the conditions of warfare. Psychotherapy is perhaps regarded with suspicion and distrust by some of the medical profession, either on account of its innate intangibility, the lack of definite proof of its hypotheses, or the possibilities of harm which might result from its exploitation by unqualified and unscrupulous persons. A moderate and carefully reasoned review of the subject is therefore refreshing, as there is still doubt as to its scope and limitations and the class of cases to which it is applicable. Dr. Millais Culpin gave our readers last week a reasonable presentation of the present position of psychotherapy. We would add that if psychotherapy is to play an important part in the future of medicine, it must find a place in our medical schools. It will probably always remain a specialty, but the student should receive instruction in its elements, as he does in other special branches of medicine and surgery, and he should be expected to display such knowledge, if called upon, at the time of his final examinations. If it is not deemed worthy of such attention, it can hardly yet be considered as a recognised branch of medicine. The tendency to send medical men for a short course of instruction, and to allow them then to practise as specialists in functional nervous disorders, is to be deplored. The psychotherapist should be a skilled neurologist and a sound general physician, for he will require expert knowledge before his doctrines can carry weight that such conditions as asthma are functional nervous disorders and amenable to treatment by mental exploration.

FOOD POISONING.

IN hot weather the thoughts of a medical officer of health naturally turn to the possibility of food poisoning and, if he lives in one of the larger towns, seldom is his anticipation unrealised, although many outbreaks never come to his notice. Frequently his first intimation is a note in the local press of a death from so-called ptomaine poisoning, with the consequent inquest and publicity. The more or less accidental fact that one or more of the cases ended fatally is often the only determining factor between official cognisance and investigation on the one hand and an entire absence of knowledge of the existence of an outbreak on the other. It is important to realise the complete lack of machinery for the official recognition of these outbreaks, mild or severe, as the extensive number of outbreaks which must occur and which remain uninvestigated is undoubtedly one important contributory reason why so much in their ætiology remains unexplained. Another factor retarding a fuller knowledge is the continued use in the lay press, by medical men, and even by health officers, of the term ptomaine poisoning, which suggests changes in the nature of putrefaction as in some way ætiologically concerned. Such a conception diverts inquiries into channels which lead nowhere and prevents investigations which might throw essential light upon paths of infection. Objection to its use is not purely academic, since its retention is a hindrance to progress. Dr. W. G. Savage has dealt decisively with this matter in his recent book on Food Poisoning and Food Infections. He pointed out that ptomaines are late degradation products of protein decomposition only produced when food is far too nasty to eat, that there is no evidence that ptomaines or other toxins produced by the breaking and maintain a hospital atmosphere convincing to the sufferers, to their friends, and not least, to the officials who have charge over them. The insane would then be regarded as patients rather than prisoners, even in those cases where the primary object of their segregation is the protection of society; when once detained, their restoration to health is alone important. This is the acknowledged atmosphere at hospitals for infectious diseases and might become universal at mental hospitals. On the preventive side, the Board deplores the collapse of Dr. Addison's Miscellaneous Provisions Bill in so far as its rejection involved a clause relating to the treatment of incipient mental disorder. There seems little doubt that some at least of the 22,373 new cases, admitted to institutions or under single care during 1920, could have been saved from certification had there existed some way of dealing with them in the early stages. This figure and that of the discharges cured, relieved, or "not recovered" (the destination of these 3276 persons remains obscure, unless transfers are included under this heading), show very little variation from those of the previous year. The total increase of 3580 in notified insane persons under care is accounted for mainly by a decrease in the death-rate. Recoveries numbered 7206, or 32·21 per cent. of the total direct admissions.

The condition of the patients in public asylums and the arrangements for their care and treatment have, as a rule, proved satisfactory to the Commissioners at their annual visits. Complaints of harshness or rough usage have been rare, and after searching inquiry justification for such complaints appears to have been even rarer. Dissatisfaction with the quality, monotony, and cooking of the food supplied seems to have been more widespread, and in some instances justified; the Board has pressed for improvement in this matter. The desirability of the nursing of male patients by women having been questioned, the Board has carefully considered this subject and concludes that under suitable circumstances the arrangement may be markedly beneficial. On the result of the special inquiry into the conditions and treatment of service patients in Prestwich Asylum we have already commented;[1] other criticisms have also been carefully investigated, a useful result being the unqualified condemnation of cold baths as correctional treatment. Considering the number of suicidal cases under detention, the number—22 persons—who managed to kill themselves while in residence does not seem high, especially as 15 of these were not regarded as suicidal; five others were so trusted as to be allowed about by themselves on parole, and two only were known to have active suicidal impulses. The cases of dysentery (1085) were fewer than those recorded for any year since 1908, when they numbered 1068. The lack of institutions for mental defectives remains an acknowledged blot in our system of dealing with abnormal members of the community. When employment is restricted it is the feeble and inefficient who suffer first, and, moreover, the presence of a large number of unprotected feeble-minded women must inevitably lead to the spread of venereal disease. Recognising that the need for national economy will prevent any direct advance on these lines at present, the Board urges local authorities at any rate to proceed with and to complete the work of ascertainment, in order that when funds permit no time shall be lost for lack of information.

Appendices contain statistics of the patients resident in asylums, hospitals, and houses, and of the expenditure incurred on their behalf, and also lists of the county and borough asylums, hospitals, and licensed houses with names of medical superintendents, clerks, and so forth; while in a supplement 15 pages are devoted to details of scientific research work. Inasmuch as the greater part of this work has been or will be published elsewhere, this space might with advantage have been allocated to extracts from the Commissioner's reports of their annual visits. Publication of Part II. of the report, which includes these, has been suspended for reasons of economy; certain statistical tables, also omitted, will be available for inspection in the offices of the Board. The reports of the Commissioners are, it is stated, mostly printed in the annual reports of the several institutions, but they would form instructive reading when taken collectively, and we regret their omission from an otherwise clear and adequate volume.

RECENT OPHTHALMOLOGY IN FRANCE.

THE French genius for elegant precision makes ophthalmology a congenial study. Dr. F. Terrien gives us a useful summary[1] of the progress of ophthalmology in France for the last year. Many of the subjects dealt with bear relation to general medicine and surgery. According to Prof. Achard, the most constant symptom of encephalitis lethargica is paralysis of the accommodation. The papilla is sometimes, but not always, affected with a moderate degree of neuritis. The anatomical seat of the lesion is usually the mid region of the mesencephalon round the aqueduct of Sylvius, when hæmorrhages are found near the vessels. In a case of retro-bulbar neuritis in a girl of 12, Dr. Netter found an alteration in the blood, the red corpuscles being reduced to one-half and the white being increased to threefold the normal, the condition being ameliorated by treatment directed to the anæmia. In a case of irido-choroiditis, an examination of the blood revealed the meningococcus some days before the supervention of any symptoms of meningitis. An observation recorded by Dr. A. Tournay in 1917 that inequality of the pupils is a physiological phenomenon when the eyes are directed to either side has been confirmed, the eye which is directed outwards towards the temple having the larger pupil. The fact that the phenomenon is found not only in healthy eyes but in blind ones points to its being not a true reflex but an associated movement of the pupil like contraction to accommodation. Coming to more exclusively ophthalmic observations, Morax and Fourrière record the results of sclero-iridectomy in hospital practice. In 16 cases of acute glaucoma, Holth's operation was performed in 12 and Elliot's in three. Tension was reduced to normal in all, but Elliot's method proved more efficacious in producing a filtering cicatrix. In subacute and chronic cases the same held good roughly. After 12 Lagrange operations there were 3 filtering cicatrices, after 22 Holth operations 6, and after 41 Elliot operations 22 filtering cicatrices. Late complications were rare, numbering only 5 after 500 operations.

SIR Frederick Andrewes and Sir Cuthbert Wallace have been appointed to fill the vacancies on the Medical Research Council created by the retirement in rotation of Mr. C. J. Bond and Prof. William Bulloch. The new appointments date from Oct. 1st.

THE Dental Section of the Students' Guide, for which space could not be found in our issue of August 27th, appears in our present issue. We commend it to the attention of the parents and guardians of intending dental surgeons. The future of dentistry is bright with possibilities.

WE print on p. 732 the names of some hundreds of medical men and women whose present addresses are not known to the Registrar of the General Medical Council. These practitioners are running the risk of having their names removed from the next issue of the Medical Register, and they should take immediate steps to keep their registration entry up to date. Removal from the Register has sundry inconvenient consequences on which we have often insisted.

---

[1] THE LANCET, 1920, ii., 1153.

[1] Paris Médical, Sept. 3rd, 1921.

The case seen by the writer in the Philippines was in a man who had come from the United States and who had never before been abroad, and it is concluded the infection was picked up there. The only cases which cannot even indirectly be connected with the war are two described by Porter in natives of South Africa. It remains to be seen whether the parasite which has been distributed about the world will now take a firm hold in distant countries with creation of new endemic centres. There appear to be four other coccidia of man, but they belong to the genus *Eimeria*, like the common coccidium of the rabbit, and are much more rarely met with than the *Isospora*. As regards the investigations recorded by the writer, he has little new information to add to what is already known. He has shown, however, that the oöcysts of *Isospora* can withstand exposure to a tropical sun for three hours, during which complete desiccation of the material in which they occur takes place. The oöcysts of coccidia are notoriously resistant structures and complete drying does not prevent the development which must take place outside the body in order that they may bring about infection when swallowed by another human being.

SILICOSIS AMONG STONEMASONS.

THE discovery that dust-phthisis is only associated with the inhalation of silica dust narrowed the issue in relation to this disease so that the claim for compensation of workers became irresistible. The provisions of the Workmen's Compensation Act, 1906, were found not to be applicable to a disease so slow in onset; moreover, experience had shown certain defects in the working of this Act. Powers were therefore obtained in 1918 to grant compensation for dust-phthisis, or, as it should more correctly be called, silicosis or silicosis complicated by tuberculosis. Under the new Act different machinery is established to meet the liability imposed; any industry brought under its provisions is called upon to insure itself by some approved scheme to which all members of the industry are obliged to belong. Liability can no longer be transferred by insuring with some company; action on these lines in the past has not resulted in employers looking upon the liability as an incentive to preventive measures. The first scheme accepted under this new Act, that applying to the "refractories" industry, has made medical supervision of the workers, as well as compensation claims, a charge upon the employers. The medical supervision established is exerted by the officers of the tuberculosis authorities in the areas where the industry is carried on. Probably similar provision will be made in schemes made applicable to other industries as the powers of the 1918 Act are extended by order of the Secretary of State. Steps in this direction are already being taken.

The Safety and Welfare Committee of the Industrial Council for the Building Industry, of which the members were directed in November, 1920, to consider whether stonemasons should be brought within the scope of the Workmen's Compensation (Silicosis) Act, 1918, have now presented a preliminary report on the subject. A memorandum was prepared for the committee by Prof. E. L. Collis, and communications were sent to various associations and bodies concerned with the work of stonemasons; conferences were held with the Joint Industrial Council for the Quarrying Industry and with several trade-unions, and after further information from these and from other sources has been received and considered a further report will be issued. The above-mentioned memorandum is included in the report, and contains interesting details of the subject under consideration by the committee. During the years 1910–1912 there were in England and Wales 6559 deaths from all causes out of a total of 99,274 stone-getters, dressers, and masons aged 25 years and over. The normal percentage of deaths due to phthisis and fibroid disease among all males of similar ages was less than 12; at that rate about 780 masons would have died from these causes, whereas 1135 masons actually died—an excess of 355 cases in three years. Had the Compensation Act applied to masons it is reasonable to suppose compensation for death would have been payable for at least this number, together with compensation for various degrees of disablement in a larger number of cases. The Act, framed for provision of compensation to persons suffering from silicosis and from silicosis complicated by tuberculosis, applies only to such industries and processes as may be determined by the Home Secretary. The inhalation of silica dust results in a high incidence of fibroid disease, and of phthisis which frequently is implanted upon it, among gold-miners, tin-miners, ganister-miners, and brick-makers, all of whom deal with quartzite rock; among grinders of metal, who use sandstone wheels; among potters and flint-knappers, who work with flint; and among the stonemasons in whose interest the inquiry was particularly undertaken. Of stones used in building, sandstones contain silica in high proportion, granites contain a low proportion, and limestones are practically free. Thus the distribution of deaths among masons is strikingly irregular, depending on the district inhabited and the stone worked. In order to avoid misleading inferences due to the age-distribution of any particular class of worker, the Registrar-General has prepared figures for a "standard population"—i.e., the actual number of males of all classes living at the various age-periods—enabling fair comparison to be made between the respective death-rates of masons and of the general population. The figures afford material for considering whether or not to include members of the building industry under the workings of the "Silicosis" Act.

A MEDICAL BENEFACTOR.

THE sudden death on Sept. 22nd from heart disease of Sir Ernest Cassel has removed a man with a natural aptitude for acquiring wealth and the rare faculty of bestowing it where needed. Born in 1852, the son of a Cologne banker, he became the friend of British medicine. Only in the spring of this year he gave £225,000 to found and endow at Penshurst a hospital for functional nervous disorders. He was a liberal contributor to the Red Cross and to King Edward VII. Hospital Fund for London, twice giving £50,000 to the Fund. He built and endowed the sanatorium at Midhurst, which bears the name of King Edward VII., and made it possible to start the Papworth Industrial Colony for Consumptives. The Radium Institute owes largely to him and to Lord Iveagh its supply of that precious element, amounting to several grammes. Other benefactions, not so well known, were no less well placed.

CAUSES OF DENTAL DECAY.

THE Medical Research Council, in consultation with the Ministry of Health, have appointed the following Committee for the investigation of the causes of dental decay: Prof. W. D. Halliburton, M.D., F.R.S. (chairman); Mr. Norman G. Bennett, M.B., L.D.S.; Dr. Leonard Colebrook; Dr. J. M. Hamill (secretary); Sir Arthur Keith, M.D., F.R.S.; Mrs. May Mellanby; Mr. J. Howard Mummery, M.R.C.S., L.D.S.; Dr. C. J. Thomas.

The appointment of the Committee will be welcomed by all who have at heart the improvement of the physique of the nation. It has been the custom for some time for medical officers of health to class dental decay among the preventable diseases, but there has been no unanimity as to how prevention is to be secured. At one time "tooth-brush drills" were fashionable, but now there is a tendency to regard the tooth-brush with some fear as a source of septic trouble and to rely upon finishing the meal with a so-called tooth-cleansing food. If tooth-brush drills have served no other purpose they have certainly acted as an advertisement—perhaps like baby shows in the case of infant welfare—of the urgent need for something to be done. An increasing body of which proposes to deal, as a start, with children of 6 and 7 years of age, including a few older children. It is hoped, however, that all children will eventually be passed under review each year. During the year it was found that only 31·8 per cent. of the children had sound teeth, as against 32·4 per cent. last year; amongst "leavers" the rate was only slightly higher, 34·3 per cent., as against 35·8 the previous year. Under the new scheme this percentage should be considerably raised in a few years' time. Normal vision was found among 77·4, and normal hearing in 99·8 per cent. Operative treatment was received by 41 per cent. of the nose and throat cases, and Dr. Charles E. Paget urges regular breathing exercises as a routine part of physical education in the schools. There were 13 definite cases of pulmonary tuberculosis in the county. Physical deformities were detected in 1 per cent. of the children examined, and in addition 1·6 per cent. were found to be suffering from heart disease. There was a marked diminution in the amount of anæmia amongst leavers, 0·67 per cent., as against 2·6 per cent. the previous year. During the year 59 schools were closed for measles—in this county the old order evidently still prevails in the case of infectious disease.

INDUSTRY AND PREVENTIVE MEDICINE:

CONFERENCE AT OXFORD.

A CONFERENCE organised by the Industrial Welfare Society was held at Balliol College, Oxford, from Sept. 15th to 20th. Here, sent by their firms, there were gathered for a few days in college life representatives of great industrial concerns, including engineering works, textile mills, railways, coal mines, shipbuilding yards, chemical works, and food factories. The programme included lectures by distinguished experts, but much solid work was done at informal meetings of groups held in rooms or in the quadrangle which were always taking place from morn to midnight; indeed a far more businesslike atmosphere was present than is usually found at scientific conferences.

The proceedings were opened by Lord **GORELL**, who announced that acceptance of office in the Air Ministry had necessitated his retirement, in favour of Lord Chelmsford, late Viceroy of India, from the Chairmanship of the Miners' Welfare Committee established under the Mining Industry Act, 1920. He dwelt upon the epoch-marking provision of this Act which makes a levy on the industry to be devoted to betterment purposes, and sets up a committee to allocate the fund. The scope of the work is to include education, health and safety, recreation, and research, so covering the whole field of human life.

Industrial Welfare as a Science.

The correctness of this view of welfare was shown by the subjects dealt with by other speakers; thus Dr. C. W. **KIMMINS** (London County Council) dealt with the educational aspect and pointed to the magnificent opportunity opening up before welfare supervisors as juvenile education under the 1918 Act comes to be carried on part-time with occupational life, and to the scope so afforded for vocational guidance. The theme so opened was developed on the industrial side by Mr. **ERIC FARMER**, who claimed that industrial psychology could be considered as a continuation of education, that it should be concerned with the human element and not be tied down by the needs of efficiency or production. Efficiency and production will certainly benefit, but this benefit should not be the only aim of industrial psychologists and physiologists: their aim should be to improve industrial activity and discover the boundary where activity becomes overstrained, the parent of irritability and discontent.

The principles of physiology underlying health were laid down by Prof. E. L. **COLLIS** (Cardiff), who pointed out the part the public can play if only these simple principles are grasped. He claimed that industrial welfare was a science, although yet a young one; he pointed out that no science could exist without means of measurement. The means in this case were labour turnover and lost time. He urged welfare supervisors to use these means and become masters of them; through them research could be carried out, without which the welfare movement could not progress. He uttered a warning that a science which was not progressing must become retrograde.

The subject of recreation was taken up by Mr. R. S. **WOOD** (Secretary of the Juvenile Organisations Committee), who dealt with camping—the rightful heritage of every boy. He placed before the conference much useful and practical information on the economic running of camps, and advocated that two or three smaller camps were more advantageous than one large one. Another aspect of recreation was delightfully demonstrated by Mr. G. J. **SHARP**, a well-known authority on folk dances and folk music. Only the best of these dances and songs have come down to us. Their value becomes apparent from the way in which they are quickly adopted and practised when once they are introduced. Play is as necessary to life as work, especially in a country long known in Europe as Merry England. Folk dances and songs which have stood the test of centuries should not be disregarded in favour of modern and less tried forms of recreation.

The Practice of Welfare.

The strength of the industrial movement was, however, made more obvious when it was spoken of by employers such as Sir **ANDREW DUNCAN** (Shipbuilding Employers' Federation), and representatives of labour, Mr. F. **BRANLEY** (Trade Union Congress) and Mr. F. S. **BUTTON**. In each case the speakers presented their point of view with what they thought some temerity. Each welcomed the welfare movement, but saw the necessity for limitation of its activities. The surprising matter was that when the two positions were thus stated no conflict whatever was found, nor did either position conflict with the work which welfare supervisors are undertaking. Both Sir Andrew Duncan and Mr. Branley considered that welfare work should concentrate upon juveniles, and only seek to permeate industry as these juveniles grow up to adult life and carry with them the spirit which welfare has implanted. Sir Andrew Duncan particularly pointed out that the outward form of welfare work was of minor importance compared with the spirit, and with recognition that there is an obligation and burden upon an industry with regard to the welfare of those engaged in it which it must itself discharge. Mr. Branley's point of view was that organised labour would give its unqualified support, without reserve, to genuine schemes of factory and workshop welfare. He looked upon the welfare movement as the ally of organised labour, working in a field particularly its own. There could be no doubt that an employer who became an enthusiast for welfare could not at the same time advocate low wages or unreasonably long hours.

Aspects of the subject put forward by different speakers were all submitted to keen discussion. The duty lay with Mr. R. R. **HYDE** (Director of the Industrial Welfare Society) to report present progress. He was able to state that the movement, which saw its birth in the stress of war-time and grew during the trade boom that followed, had held its own in a wonderful way during the unprecedented slump from which we are only just beginning to emerge. Now he could state that firms who have once adopted welfare were continuing it whatever the conditions of trade. Apart altogether from its high aims and aspirations as a branch of social service, welfare had value in providing common ground upon which employers and employed could meet in amity.

Those who attended this Conference could not help being struck by the earnestness and enthusiasm which inspired it. All present were bent upon ensuring the success of what promises to be the foundation of a new spirit of health and contentment in the industrial world.

which in 1898 was 61·0, had risen in 1905 to 75·8. About this time a Bill was introduced into Parliament relaxing the conditions under which exemptions could be obtained; and the Vaccination Act of 1907 made the getting of an exemption a mere formality, so that it was obtainable by any parent. All that the parent now does is to fill up the form and hand it to a magistrate for signature, no questions being asked by either party. In this way unthinking and selfish parents make use of the exemption clause in order to shirk their responsibilities to their children, and evade some small and temporary inconvenience to themselves. The effect of the 1907 Act has been to make vaccination in many districts a dead letter. In 1919, the last year for which figures are as yet available, the percentage of vaccinations to births had fallen to 40·6. From the statistical tables given in the pamphlet of the Ministry of Health, it appears that in the 10 years 1910 to 1919, allowing for those who have died, there still remain 2½ millions of children who have been "legally" exempted from vaccination, and who are therefore totally unprotected against small-pox. Moreover, by the operations of the 1907 Act a further 250,000 exempted children are being added every year to the unprotected population of this country. We are therefore rapidly reverting to the conditions which existed in pre-vaccination days. The pamphlet of the Ministry of Health should be spread broadcast.

THE GROWTH OF BIOCHEMISTRY.

RECENTLY we have devoted an increasing amount of space to reviews of books and journals dealing with biochemistry. Last week it was a new text-book by Dr. Benjamin Moore and an issue of the *Biochemical Journal*; this week it is the *Journal of Biological Chemistry*, which is strong on the side of technique. The recent meeting of the British Association gave great attention to biochemistry. "The Laboratory of the Living Organism" was the title of the presidential address to the Section of Chemistry, and a joint meeting of the Sections of Chemistry and Physiology was opened by Prof. F. G. Hopkins with a paper on Oxidations and Oxidative Mechanisms in Living Tissues. We are thus confirmed in the belief that biochemistry in its fullest sense is of fundamental importance not only in the daily life of every citizen, but still more in the special field of medicine. Nowadays, biochemistry is all-embracing, including as it does the fundamental principles of organic chemistry (from which it is derived); of inorganic and physical chemistry; together with such particular branches as food analysis (including the question of vitamins), sewage treatment, industrial fermentation processes, the changes occurring in blood coagulation, immunity, digestion, secretions of special glands. Few of our readers will be able to follow continuously all this modern work and the journal abstracts are offered on this account. Chemistry has always been intimately associated with medicine, but with the rapid development of the two subjects they have recently grown apart; happily, the connexion is again being established by the progress of physiological chemistry. The extension of biochemistry will necessitate modifications in the teaching in our medical schools. At present there is little or no coördination during the several years of study and even less scope for post-graduates to take up a particular branch for further knowledge and research. It is not easy to find a solution to this problem of ever-increasing demands upon teachers and students, but some radical change must be made. This alteration might consist, in the first place, in the appointment of a biochemist as professor of medical chemistry, who should coördinate and be responsible for the whole range of chemical subjects in the medical curriculum. With a suitable staff the early part consisting of inorganic and organic chemistry, the intermediate part of physiological chemistry, and the final parts of pathological chemistry and hygiene, could be welded into a succinct and shorter course than is provided at present, with the elimination of much encumbering material. At the same time the department should offer sufficient accommodation to post-graduates for special work and to permanent research workers. All needs would thus be met. Departments of medical chemistry planned on such a basis would attract younger men as assistants, who, in course of time, would become familiar with the whole range of the work and ultimately become the chiefs. The same department in our universities could undertake the general chemical course for students of botany and, if required, provide for advanced work with suitable assistance. Though organised as an independent whole, contact should be maintained with physiology, pathology, and other medical subjects. Under the existing arrangements, with each branch under the care of a separate lecturer, there is little opportunity for the several chemical teachers to become acquainted with the whole range of medical chemistry. They cannot take the proper interest in the medical side of the subject and have to seek eventually other appointments unconnected with medical science. Moreover, a chemist who has had no training in physiology lacks real sympathy with the medical curriculum and the subject of medical chemistry is stultified. If professorships of medical chemistry were founded at each medical school medical chemistry would flourish amazingly.

SPIROCHÆTES IN PERIODONTAL DISEASE.

IN the *Dental Cosmos* for September, Kritchevsky and Ségun give some interesting facts with a bearing on the pathology of periodontal disease. In syphilitics with clinically healthy gums they found no spirochætes, but of 24 cases where there was characteristic periodontal disease 22 showed spirochætes, and in 70 per cent. of these cases the spirochætes disappeared after the administration of neosalvarsan. As a result of further investigation the authors are of the opinion that spirochætes in association with the *Bacillus fusiformis* are the primary cause of all necrotic conditions of the gum margins, the process of destruction being completed by pus-forming aerobic and anaerobic cocci. The authors do not consider there is one specific spirochæte but several varieties. A number of experiments were conducted on guinea-pigs, the secretion being taken from different affections of the mouth, such as pyorrhœa alveolaris, Vincent's angina, mercurial stomatitis, and injected subcutaneously. Characteristic abscesses were obtained, sections of which showed, in the centre, pus containing cocci, spirochætes, fusiform bacilli, and vibrios. Outside this was a layer of total necrosis exclusively filled with fusiform bacilli; beyond this, again, a zone of greatly altered tissue filled with fusiform bacilli and spirochætes; then a zone with but few fusiform bacilli; and, finally, a region with pure spirochætes only. From their observations the authors came to the conclusion that in the first place there is an invasion by spirochætes which, by their toxins, prepare the tissues for the final destructive and necrotic action of the fusiform bacillus. The tissue is then secondarily infected by different aerobic and anaerobic cocci.

LUNACY CONTROL.

THE annual report for 1920 is the seventh issued by the Board of Control since its inception in 1913. In May, 1920, the bulk of the powers of the Secretary of State under the enactments relating to lunacy and mental deficiency were transferred to the Ministry of Health, and the Board rejoices not only in the administrative advantages thus gained but in the hope that this step may help to dispel prejudice and may ensure the linking up of preventive measures and after-care with curative treatment. The close association with the Ministry of Health may serve to create by Pasteur's method typical symptoms of the disease developed 40 days after the bite. The animal survived for five days. The manifestations, which were carefully observed, were almost the same as in man; the cramps could, however, be checked for six to eight hours by administration of a large dose of salvarsan (4·5 g.).

Grippe as an easy Diagnosis.

Dr. Kovacshazi has expressed the opinion that most of the cases called influenza are ordinary colds, which it has become a fad to speak of as grippe. In a number of cases in which microscopical examinations were made for the bacillus it was found once only, and that in an unsuspected case. It would be a blessing if the term "grippe" were now abandoned; it is applied to every form of affection that occurs as the result of cold weather, from cold in one nostril to terminal pulmonary tuberculosis. Grippe is a soothing diagnosis to make. It prepares the family for the worst at once. Any number of complications may occur, and the doctor can scarcely be held responsible. It would be better if the affections seen were called by descriptive names such as laryngitis, pharyngitis, and bronchitis.

Sept. 14th.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. W. S. H. Sequeira is placed on Retd. List at own request, with rank of Surg. Capt.

The following appointments are announced: Surg. Lieut.-Comdrs. A. R. Sharrod to *Collingwood;* and A. E. Malone to *Kellett* (temp.).

ROYAL ARMY MEDICAL CORPS.

Temp. Lieut.-Col. A. Simpson relinquishes his commn. and retains the rank of Lieut.-Col.

Maj. A. G. Cummins retires on ret. pay.

The undermentioned temp. Capts. relinquish their commns. and retain the rank of Capt.: R. T. G. Aickin and N. W. Furey.

J. M. Semple to be temp. Lieut.

SPECIAL RESERVE OF OFFICERS.

The undermentioned Capts. relinquish their commns. and retain the rank of Capt.: G. R. Hubbard, C. G. J. Rayner, and I. H. Zortman.

TERRITORIAL FORCE.

Maj. A. B. Sloan resigns his commn. and retains the rank of Maj., with permission to wear the prescribed uniform.

Capt. D. Dickie resigns his commn. and retains the rank of Capt.

ROYAL AIR FORCE.

Flight-Lieut. H. J. Swan relinquishes his temporary commn. on ceasing to be employed, and is permitted to retain the rank of Capt.

INDIAN MEDICAL SERVICE.

J. Rodger (late R.A.M.C.) to be Capt.

The King has approved the relinquishment of their commns. by the undermentioned officers and the grant of rank as shown: Capt. Nagendra Nath Maitra, and are granted the rank of Capt. on relinquishing their commns.: Maneck Sohrabjee Hormusjee Mody, Narayan Raghanath Satpute, Khagendra Mohan Basu, and Narayan Hari Kulkarni.

DONATIONS AND BEQUESTS.—The governors of the Manchester Children's Hospital during the past month have received donations and legacies totalling £2117, which includes a sum of £1203 from the Manchester and Salford Hospital Sunday Fund.—The late Mr. George Marsden, of Birkdale, Lancs, has bequeathed £500 to the Children's Sanatorium, Southport.—By the will of the late Mr. John Joyce, J.P., Wallasey, Cheshire, the Liverpool Royal Infirmary will receive £500, the David Lewis Northern Hospital and the Royal Southern Hospital £250 each, and the Victoria Central Hospital, Liscard, £100.—Under the will of the late Countess Eldon, of Tilehurst, Bucks, the testatrix left £500 to the Cripples' Fund of the Lord Mayor of London, £500 to the Victoria Hospital for Children, £500 to the Cancer Hospital, £500 to the Hospital for Diseases of the Heart, £250 to the Evelina Hospital for Sick Children, and £250 to the National Anti-Vivisection Society.

"Audi alteram partem."

X RAY TREATMENT OF OTOSCLEROSIS.

To the Editor of THE LANCET.

SIR,—I have read with interest Dr. J. H. D. Webster's article on the X Ray Treatment of Otosclerosis in your issue of Sept. 24th, for we must all agree with Gray's remark, which he quotes, that in this disease we are "confronted with one of the most difficult and obscure problems in modern medicine." Nevertheless, I regret that he has published his article at this early stage, for it is likely to raise premature hopes among the numerous unfortunate sufferers from this affection, and to embarrass those practitioners who do not wish to experiment with a new method until there appear more solid grounds for expecting a successful result, for the a priori reasons for believing that the early stages should be amenable to radiation treatment do not seem very convincing. As it is well known that long stationary periods occur in this disease, Dr. Webster's two cases are much too recent to base any conclusion thereon. Prof. Siebenmann himself, whose method Dr. Webster has followed, finds the results "only to a small degree positively encouraging," and wisely states that "his trial of the method has not continued long enough for him to come to a definite conclusion." Neither has he as yet published his technique, which Dr. Webster is therefore unable to quote in print. On these grounds it is wise to accentuate the note of caution which, it is fair to say, Dr. Webster sounds in his paper.

I am, Sir, yours faithfully,
HAROLD BARWELL.

Queen Anne-street, W., Sept. 24th, 1921.

THE DANGERS OF THE PUBLIC SWIMMING BATH.

To the Editor of THE LANCET.

SIR,—Your annotation on the Swimming Bath and Catarrhal Otitis in THE LANCET of Sept. 3rd, and subsequent correspondence from Dr. Dan McKenzie and Dr. F. W. Alexander have served to revive the important questions of the dangers resulting from the pollution of public swimming baths and their prevention. The subject was dealt with at some length in a paper read by me over nine years ago which was fully discussed at a meeting of the Medical Officers of Schools Association and published in *School Hygiene* in May, 1912.[1] This paper was based on bacteriological examinations of the water from a small swimming bath in use at one of the London County Council's Industrial schools. The number of boys using the bath daily varied from one to two dozen, each soaping himself over thoroughly before going in. The water was changed twice weekly, but no disinfectant was applied. The unpolluted water taken shortly after filling the cleansed bath yielded a count of about 100 organisms per c.cm., chiefly of the *Proteus* group, whereas the samples obtained after the bath had been in use for two to three days gave an average of 4000 organisms per c.cm., among which *Streptococcus fæcalis, Staphylococcus pyogenes aureus, B. coli communis, Proteus,* as well as Gram-negative diplococci occurring in normal saliva, and certain skin contaminations, were isolated and identified, alike from the polluted water and the slime deposited on the floor and sides of the empty bath. Reference was made to investigations carried out by Drs. G. H. Pearce and Sutherland[2] on the water of the public swimming bath at Batley in Yorkshire in June, 1910, where the degree of microbic pollution was found to vary considerably, according to the class and number of persons using the bath and their condition of cleanliness. Bacterial counts ranging from under 3000 to about 300,000 organisms per c.cm.

Public Health Services.

THE MARRIAGE BAR.

THE injustice that may be involved in the application of a general principle to a particular case is well illustrated by current events in the Borough of St. Pancras. The Borough Council recently passed a resolution to terminate the appointments of married women on their staff whose husbands are in receipt of salaries sufficient to support their wives. This resolution is now found to apply to the assistant medical officer for maternity and child welfare, and the Ministry of Health, which pays half her salary, was asked to sanction a request to Dr. Gladys Miall-Smith to resign her post in view of her recent marriage. The Minister observed in reply, that, while the proposal did not require his sanction, he considered that in view of the special qualification and capability of Dr. Miall-Smith, and the present shortage of women medical officers trained in this work, the Borough Council would be well advised to retain her services provisionally if their rules permitted. The case as put by the assistant medical officer herself was, briefly, that no marriage disqualification or resignation clause was inserted either in the advertisement of the post which appeared in the medical press in January, 1920, or in the forms of application or appointment submitted to her; that in fact a married woman was among the three applicants finally selected by the Public Health Committee. She points out that the attitude of the council up to the present has led her to suppose that they concurred in the general view that marriage was an added qualification for any work connected with maternity and child welfare, inasmuch as a large proportion of the doctors appointed and paid by the council to work at the infant-welfare centres, and in particular those recently appointed, are married medical women. Moreover, there being no unemployment problem at the present moment amongst medical women, the question of her keeping a single woman out of employment does not arise. Since her appointment Dr. Miall-Smith has obtained the D.P.H., thus further qualifying herself for the work she undertakes. Letters in support of her claim were received by the Council from the British Medical Association, the Society of Medical Officers of Health, the Federation of Medical Women, the National Association of Local Government Officers, the London Society for Women's Service, and the superintendents of local welfare centres. The arguments in these letters were largely amplifications and extensions of those advanced by Dr. Miall-Smith herself, except in so far as they emphasised her exceptional qualifications, efficiency, and local popularity. The British Medical Association urged that, whatever the council's attitude on the general question of the employment of married women, there could be no doubt of their suitability for child-welfare work, and asked that the council should seriously consider the advisability of retaining Dr. Miall-Smith's services. The Federation of Medical Women spoke of the special suitability of work with fixed hours for married women, and of the value to the community of one who may have intimate knowledge of children of her own; also of special arrangements whereby absence for confinement would involve no loss to ratepayers. Eventually, after some discussion, the decision to ask Dr. Miall-Smith to resign was upheld. It remains to be seen whether the council will now proceed to ask for resignations from the married women doctors employed by them at the local welfare centres and whether they will presently extend this attention to married men in their employment whose wives are in receipt of salaries sufficient to support their husbands.

WOMEN PRACTITIONERS AND A RESTRICTED PANEL.

Early in the year four women practitioners on the London medical list, preferring not to undertake the treatment of men patients, were deprived of 7½ per cent. of their share in the practitioner's fund, and this in accordance with the terms of the 1921 contract as interpreted by the London Insurance Committee. We expressed a doubt at the time whether Section 5 of the Distribution Scheme was intended to have this construction placed upon it. Later the Committee decided that, subject to the approval of the Ministry of Health, a reduction of 3¾ per cent. only in the practitioner's credit should be involved in the limitation of the panel list to patients of one sex. The Ministry have approved the amendment of the clause by the addition of the words: "by 3¾ per cent. in the case of a woman practitioner limiting her list to patients of her own sex." As the converse case is hardly likely to occur the Ministry presumably decided to legislate in this instance for women only.

SCHOOL MEDICAL SERVICE.

Leicestershire.

IN this county the school nurses carry out the duties under the Notification of Births Act; they are also inspectors of midwives and infant life protection visitors. The school doctors, too, are medical officers to the infant welfare centres, in this way ensuring coöperation of effort in dealing with children from birth to the end of school life. Dr. T. Robinson, however, has to deplore the number of changes in the nursing staff. During the past year over 12,000 children were submitted to routine examination; of these, 681 required treatment for defective vision, 487 for enlarged tonsils and adenoids, 673 for dental disease, and 93 for ear troubles. Six hundred and forty-four of the defective vision cases obtained treatment, 473 of those suffering from enlarged tonsils and adenoids, 290 of them being operated on. Out of 6899 children dentally inspected, 3092 were referred for treatment and 2791 actually treated. A central dental clinic is about to be opened in Leicester for the treatment of children on Saturdays; it will be interesting to see with what success, as Saturday clinics so far have not proved popular.

Leeds.

The total cost during the past year for medical services was high—just over 8*s*. per head of attendances at the elementary schools. The efforts of the late Dr. W. Angus, when medical officer, are bearing fruit and Leeds is coming into line in respect of care for its children. Children found to be defective seem to be given some six weeks in the hope that the parents will provide remedy; then they are marked off to clinics—Leeds excels in clinics. Seven of these had 174,446 attendances, and this total apparently does not include cases of enlarged tonsils and adenoids, for which the authority does not provide treatment. On the fate of these "no definite information is available." Dental attendances were 16,735, making a total of over 190,000. The work of the school nurses appears very satisfactory; two-thirds of their time is spent in the clinics, and only one-tenth in home visits. This determined effort to clear diseased conditions out of the schools is not equalled by preventive measures, for although there are some playground classes and nine play centres Leeds has no open-air schools, which would be much appreciated in a town. Other lacunæ, such as absence of schools for cripples and for epileptics and classes for the dull and backward, are also noticed. A house has, however, been purchased to serve as a nursery school. The number of children examined during the year was 26,759 in the elementary schools and 1792 in the secondary and special schools. The total number of cases referred for treatment was 11,528, defective vision accounting for 2360 and uncleanliness for over 3000. Ten per cent. of the secondary school children were suffering from malnutrition. It is unfortunate that the medical officer does not attend the advisory committee for juvenile employment, where his advice would be helpful.

Northamptonshire.

The most noteworthy feature of the school medical work this year is the new scheme for dental treatment designed for radiography or fluoroscopy, is essentially unfitted for the work, as it is constructed to give as large a *quantity* (milliamperage) as possible through a medium tube for a short time, while for these treatments a small milliamperage, through an excessively hard tube, is required for hours consecutively. The method of measuring the rays is also special, as these very hard rays—filtered as they are through 0·5 mm. zinc (=about 12 mm. aluminium) cannot be measured by Sabouraud pastilles, which are, according to Prof. Sidney Russ, "hopelessly transparent to very penetrating types of radiation." Dr. Charles Guilbert, in his recent work on deep therapy, agrees with the Erlangen school that the only reliable method of measuring X ray dosage is that based on ionisation (iontoquantimeter). It is only by some such means as this that it is possible to estimate accurately what percentage of the dose falling on the skin is absorbed, and is therefore of therapeutic value at varying depths in the tissues.

Deep therapy, similar in principle though at times differing in the details of the technique, is being practised at most large continental hospitals; there are five installations suitable for the treatment in constant use at the late Prof. Wertheim's clinic in Vienna. From what I saw at Erlangen I am of opinion that this treatment of malignant disease offers, in suitable cases, as good results as regards cure and the absence of the likelihood of metastasis as Prof. Wintz claims.—I am, Sir, yours faithfully,

J. CURTIS WEBB,
Hon. Radiologist, Gloucester Royal Infirmary.
Sept. 22nd, 1921.

THE COUGHING CUP.

To the Editor of THE LANCET.

SIR,—I should like to endorse the suggestion of the "coughing cup" for the prevention of tuberculosis contained in the letter of Dr. T. M. Allison in THE LANCET of Sept. 17th. But I would go one further and suggest that everyone suffering from a cough should use a coughing cup. Post-mortem findings and the Pirquet reaction support the hypothesis that the tubercle bacillus is ubiquitous among civilised communities and that everyone is infected at some period of his existence and possibly a danger to the community while carrying the organism. I further suggest that the cough spray is the *chief* mode of infection and that the apparently non-tuberculous, being in the large majority, are responsible for the widespread dissemination of the bacillus to at least an equal extent as the obviously tuberculous. A few of the apparently non-tuberculous are incipient cases without physical signs or signs sufficient to bring them under the scrutiny of a medical officer, but the great majority of this class, although reacting to the Pirquet test, never develop the disease as it is known to the clinician. It has been demonstrated how the meningococcus can pass through a community under certain conditions—namely, those of overcrowding and bad ventilation, and that the process is accelerated by the presence of coughs and colds. The inference that the tubercle bacillus, which is so widespread in its distribution, is disseminated in the same manner as the meningococcus is strongly supported by facts.

I am, Sir, yours faithfully,
D. H. C. GIVEN, M.D., D.P.H.,
Sept. 19th, 1921. Surgeon-Commander, R.N.

ROYAL MICROSCOPICAL SOCIETY.—A conversazione will be held at the Mortimer Halls, Mortimer-street, London, W., on Wednesday next, Oct. 5th, from 7.30 to 10.30 P.M., the President, Prof. John Eyre, receiving the guests. A preliminary programme of meetings for the coming session has been issued. The papers to be read include one by Dr. Lancelot T. Hogben, entitled Preliminary Account of the Spermatogenesis of Sphenodon; a paper by Prof. Eyre on Microscopy and Oyster Culture, and one by Mr. Joseph G. Barnard on the Future of the Microscope in Medical Research. Further information can be obtained from the hon. secretaries, Mr. J. G. Barnard and Dr. J. A. Murray, 20, Hanover-square, London, W. 1.

Obituary.

CAREY PEARCE COOMBS, M.D. LOND.

THE death of Dr. Carey Pearce Coombs, of Castle Cary, Somerset, has removed a familiar figure from the ranks of the medical profession in the West Country. Dr. Coombs was born at Frome, where he went to school. At the age of 14 he was apprenticed to his uncle, who was practising in the same town, and two or three years later went to St. Mary's Hospital, Paddington. This school was then in its infancy, and the successes gained by the young Coombs at the University of London (honours in several subjects in the First M.B., and a final pass at the age of 21) were all the more welcome. During these years he lived with and assisted Mr. Fitzpatrick in Lisson-street, near the Edgware-road. He was assistant demonstrator of anatomy at St. Mary's, and subsequently house surgeon, but any hope of promotion to the honorary staff was frustrated by the death of his father, which made it necessary for him to take a share in his uncle's practice in 1865. He went to live at Beckington, near Frome, and in 1866 married Mary Leslie, daughter of Mr. William Franklin, of Coventry. In 1867 he took a small practice, one of several then existing in the town of Castle Cary. After passing his M.D. in 1869, Coombs gradually absorbed the other practices, and was in active work till 1911, when he retired, after a seven years' partnership with Dr. David Price who succeeded him.

During this period of 44 years he endeared himself to the whole neighbourhood, not only by his professional efficiency, but also by his kindly and unselfish disposition. He held various local appointments, among them the medical officership to the Castle Cary district of the Wincanton Union, and the Ditcheat district of the Shepton Mallet Union. His principal contributions to medical literature dealt with electro-therapeutics, in which he took the greatest interest. In 1875 Sir William (then Dr.) Broadbent, in his preface to the seventh edition of Tanner's "Practice of Medicine," stated that the section on electro-therapeutics had been written by his "friend and late pupil, Dr. C. P. Coombs." Twenty years later the subject of his presidential address to the Bath and Bristol Branch of the British Medical Association was "Galvanism in the Treatment of Neuritis," an address which he expanded into a small volume, published in 1896. Although he held no public health appointment, he was largely responsible for securing for Castle Cary a safe water-supply, and was the first chairman of the water company formed in 1908.

Throughout his life the character of Dr. Coombs was marked by a singular catholicity of temper as of taste. Brought up as a Free Churchman, he attended the Congregational Chapel at Castle Cary from the time when he settled in the town until his death. For nearly 50 years he was treasurer to the Chapel, and in many other ways gave his services to the cause. In spite of this fidelity to conviction—a course difficult for a young doctor to take in a country town 50 years ago—he made numerous friends among those of other persuasions, and was wont to say that the proudest moment of his life was that in which he had been helped into his overcoat by four rural deans! For many years he was president of a non-sectarian men's adult school. He was fond of music, and for nearly 30 years was president of the local choral society which he helped to found. Among his other hobbies were painting and wood-carving. He was no mean archæologist, and in a neighbourhood affording unlimited material for such studies he was an unerring guide.

After his retirement in 1911 he was made a Justice of the Peace, and chairman to the Castle Cary school managers. He was also chairman of Messrs. John Boyd and Co., Ltd., for many years, and trustee of the Jubilee Cottages founded by that firm for their superannuated workpeople. His personal appearance

FOOD POISONING OUTBREAKS:

MEMORANDUM ON THE COLLECTION AND TRANSMISSION OF SAMPLES.

A CIRCULAR letter issued by the Ministry of Health to medical officers of health on Food Poisoning Inquiries includes a memorandum by Dr. W. G. Savage, setting forth how to obtain and transmit specimens. Outbreaks, it is stated, differ so much in character that uniformity of requirement in regard to specimens is not possible, but the following should be collected.

(1) *Any Portions of the Supposed Peccant Food.*—These should be actual portions remaining over from the food which caused the illness. Even small scraps, remains in tins (if a tinned food) are better than nothing. Samples of food of similar origin are usually of little assistance but occasionally are useful.

(2) *Post-mortem Materials from Fatal Cases.*—The spleen, pieces of liver, piece of small intestine, kidney, are the most useful. The stomach (ligatured) with unopened contents is valuable if metallic poisoning is suspected, but not of much use otherwise.

(3) *Pathological Material from the Cases.*—From all cases, and especially when (1) is not available, and (2) only problematical, endeavours should be made to collect and transmit material from the actual sufferers while in the acute stages. The samples should be excreta samples and vomit. Of these, excreta samples are both the easier to obtain and the more valuable.

(4) *Samples of Blood for Serological Examination from the Sufferers.*—There is no urgency about these samples since any serological reactions persist for many weeks, while in any case they will not develop until a week or more after the onset. It is better, therefore, to wait to collect these samples until after the bacteriologist has the other samples, and also the preliminary information as to the outbreak, so that he can indicate exactly what he requires.

Transmission.

Outfits are available at the Bristol Laboratory, but usually there will not be time to send for these, and the transmittors must use their laboratory outfits or an emergency one. Excreta specimens can be sent in clean wide-mouth bottles. The food can be put in a clean tobacco tin. The organs from fatal cases should each be wrapped in a piece of clean cloth wetted and wrung out (only damp, therefore) with 1 in 500 corrosive sublimate solution. All the organs can be placed so wrapped in one large tobacco or other tin. Outfits for blood samples will be sent from the laboratory.

If possible, the samples should be sent packed in ice. An impromptu ice box can be made by using a fairly large biscuit tin, and packing the tins and bottles in one side of this and filling the other part with dry ice in small pieces. The tins and bottles must be secured from rolling about when the ice melts, by means of cloths and wood partition, or other device. The biscuit box should be packed in a wood box with at least two inches everywhere of sawdust between the two boxes. If ice is not procurable the samples must be sent without it rather than delay.

Samples should be sent by passenger train to Mr. Bruce White, Pathology Department, University of Bristol, who should be informed at once by telegram of their despatch, and, if possible, of the time of arrival, so that everything may be in readiness at the laboratory.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The Prevention of Summer Diarrhœa.

Dr. Blumenfeld, who is in charge of a large children's hospital, had this year an unusually large number of cases of diarrhœa under his care. He ascribed the increased incidence of the complaint to the excessive heat, which reduced infantile resistance and promoted the multiplication of bacteria in milk. In an address on the subject he outlined the general care of the infant during this period, the necessity of open air, cool clothes, cleanliness, properly prepared milk, and suitable intervals of feeding. He detailed the contents of a leaflet to be distributed to mothers and physicians, and suggested instruction in the schools, especially the high schools, of matters relating to infant hygiene, and also proposed that the milk commissioners now appointed in several cities should be increased in number. He suggested the idea that a municipal model dairy, under medical supervision, and a milk plant which would sell to the poor at cost price, should be established in every city. He condemned wholesale pasteurisation, as the numbers of bacteria in milk actually increase under this treatment, whereas home pasteurising does not have the same effect.

The Heroin Habit.

Dr. Vidakovich notes the variety of cases of addiction to heroin, and reports one occurring in his practice. The patient was a spinster, aged 41, of nervous heredity, to whom the drug had been given as an anodyne with the assurance that there was no danger of forming a habit. She continued to take the drug after the original indication for its use had disappeared, and when coming under treatment was giving herself 0·06 g. hypodermically in divided doses daily. A cure resulted from immediate withdrawal with symptomatic, sustaining, and eliminative treatment. The abstinence symptoms were, however, so severe that Dr. Vidakovich observes that in future he would resort to gradual withdrawal.

Morphine-Scopolamine Narcosis.

Dr. Frater, surgeon at a large provincial hospital, one of the most conservative operators in the country, states that morphine and scopolamine alone as a narcotic are hardly ever safe, the dose of the former drug being too high. Small doses are, however, highly to be recommended if followed by one of the usual anæsthetics (morphine hydrochloride, 0·01 to 0·02 g.; scopolamine hydrobromide, 0·0005 to 0·001 g., in fresh solution). Either chloroform or ether may be used, but the advantages of ether are perhaps more marked. The excitation stage is shorter, less anæsthetic is necessary, salivation is never troublesome, and the danger of post-operative pneumonia is considerably diminished. Some 800 cases have been reported, with a mortality of 1 per cent., but many of the patients were already in a moribund condition when operated on. It may also be advisable to resort to the two drugs in smaller doses in Schleich's infiltration anæsthesia.

Headache the only Symptom of a Case of Malaria.

Dr. Sümegi, who recently returned from imprisonment in Russia, reports a peculiar case of malaria, without temperature symptoms, occurring during a severe Siberian winter. The patient was his brother, a sergeant; the only symptom he complained of was headache, which appeared each forenoon and lasted a few hours. The patient had no previous malarial infection. Dr. Sümegi had no occasion to examine his brother's blood, nor did he suspect the presence of malaria. However, when the brothers were returning through Moscow, Dr. Sümegi visited a friend of his, a hospital bacteriologist, who advised an examination of the blood. This was accordingly done; no perfect organisms were shown, but numerous malarial spores were present, which rapidly disappeared, together with the symptoms, under quinine. Dr. Sümegi regrets that the blood examination was not made earlier, and the exact character of the parasite determined; the appearances indicated the tertian organism.

Favourable Health Conditions in Budapest.

The death-rate in this city for the first six months of this year was considerably lower than for the corresponding period in 1920; but for scarlet fever the figures would have been the lowest for many years. The death-rate for the past six months was 19·75; for 1920, 21·68; and for 1903, 19·11.

Rabies in a Horse.

Rabies is supposed to be uncommon in horses. In a small village among the Carpathians a horse was recently bitten by a rabid dog. Although inoculated

MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS.

WE are requested by the Registrar of the General Medical Council to give publicity to the following list of medical practitioners who have not replied to his inquiries as to the accuracy of their addresses. The list includes all untraceable names on the colonial and foreign lists, but only those from P to Z on the body of the register, as it is only this section which has come under review this year. Anyone who finds his or her name included in this list should communicate immediately with the Registrar (E) of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1.; or (S) of the Scottish Branch Council, 20, Queen-street, Edinburgh; or (I) of the Irish Branch Council, 35, Dawson-street, Dublin.

were obtained on different occasions. Among them were found coliform or intestinal flora, *B. enteritidis sporogenes*, *Staphylococcus pyogenes aureus*, *Streptococcus pyogenes* and *Proteus vulgaris*. The bacteriological evidence of bath water pollution provided by these two independent investigations, it was claimed, pointed to the possible causation of such inflammatory conditions as otitis media, conjunctivitis, &c., and the further possibility that the contaminated bath water might well become a vehicle of other infections, notably diphtheria, influenza, tuberculosis and enteric fever, despite the want of clear proof of such mode of infection. The purification of swimming baths was fully discussed, and in particular the method employed in Poplar, as introduced by Dr. Alexander and referred to in his letter of Sept. 17th, was strongly advocated for universal use. Its value was also emphasised in the discussion following the paper and the whole subject was recommended for further investigation. This recommendation was met in November, 1912, by the report on "The Purification of the Water of Swimming Baths" issued by a committee of the Royal Sanitary Institute, as already mentioned by Dr. Alexander. In this report the risk of massive infection to bathers by swallowing the recently ejected mucous discharges of persons suffering from disease, and the ease with which among other results catarrhal or septic conditions of the nose, throat and ear might supervene, were pointed out. The treatment of bath water by hypochlorite of magnesia solution, or the electrolytic fluid used at Poplar, was fully investigated and very much impressed the committee with the good results obtained.

Since the date of this publication and until the recent correspondence in your columns the subject, though undoubtedly one of considerable hygienic importance, has been allowed to lapse in this country. It has, however, received some attention in America. S. C. Markley, in his M.Sc. thesis at Yale University in 1913, described the value of the use of chloride of lime in the purification of swimming baths and the method of its application. In January, 1917, Dr. W. A. Manheimer[3] published a paper in the *American Physical Education Review* from the Research Laboratory of the New York Department of Health on a "Comparison of Methods for Disinfecting Swimming Pools." His report included results of investigation as to:—

1. Ultra-violet light, on the value of which he was unable to form a decided opinion.
2. Lectrocide, obtained through electrolysis of brine and mainly composed of sodium hypochlorite—found to possess a high coefficient of disinfection.
3. Copper sulphate—1 part to 100,000 of the water—showed the least efficiency and highest cost of all chemicals used in pool disinfection.
4. Chlorine gas, injected into tap water feeding the pipe to the pool, was proved to yield high efficiency at very low cost and was easily applied. Calcium hypochlorite was found for similar reasons to be very efficacious.
5. Ozone was thought likely to be of considerable value and was to be the subject of future tests.

In the same publication a year later "The Sanitary Aspects of the Swimming Pool at Cornell University" were considered by Henry N. Ogden[4] and the few instances of alleged transmission of communicable disease were quoted. Among these were the prevalence of influenza, colds, sore-throat, and occasionally pneumonia, restricted to users of the swimming tank in the North Western University, noted by W. L. Lewis, and a mild epidemic of typhoid fever ascribed to swimming bath infection and reported by R. J. Reece in the Local Government Board Reports, 1908–1909, also affections of the nose and ear among members of the swimming team at Brown University in 1910 described by Bunker (comparable, indeed, to the recent outbreak of conjunctivitis and catarrhal otitis among members of the swimming club at Freiburg as described by Amersbach, the subject of the annotation in THE LANCET of Sept. 3rd). Ogden's paper includes an account of bacteriological tests applied to swimming bath water at Cornell and a number of other American Universities, together with the methods of disinfection employed. The results were described as unqualifiedly convincing of the value of the disinfectant used (solution of chloride of lime yielding one and a half parts available chlorine per million gallons) and of the good quality of the water so treated. As far back as 1898 an outbreak of acute contagious ophthalmia was described by Yaginsky as having been conveyed by children in a public bath in Berlin, where also in 1899 the spread of granular ophthalmia was reported as due to swimming bath infection. A similar connexion was suggested as responsible for the occurrence of conjunctivitis among children at one of the London industrial schools in 1912, but the evidence was not conclusive. The risk of ear infection which has been strongly urged by Dr. Dan McKenzie is no fanciful one, and is incurred alike in the public swimming bath and in sea bathing. Attention has been drawn to the latter by H. V. Blackwell in a paper published in the *Medical Record* of 1916, entitled "The Salt-water Ear," and a warning is uttered against the danger of otitis media, occurring particularly among those with a history of previous ear trouble or subject to otorrhœa.

At the risk of trespassing too much on your valuable space I would quote the following case of acute meningitis which I saw some 12 months ago in a girl of 14, who provided in striking and tragic fashion clear evidence that the swimming bath was *directly* responsible. In previous good health and with no history of past ear trouble the girl visited a public swimming bath on a Thursday, earache being complained of on the next day. On Saturday afternoon, when I first saw her, the left ear was discharging, she was unconscious with definite signs of meningitis, further demonstrated by the fluid obtained from lumbar puncture. Death occurred the following morning.

It is much to be hoped in the interests of the very large numbers using the public swimming baths that the publicity which the correspondence in your columns has given to the subject of swimming bath pollution may lead to the universal adoption by the responsible authorities of some such system of purification as is so successfully carried out at Poplar.

I am, Sir, yours faithfully,
J. GRAHAM FORBES.

THE ERLANGEN TECHNIQUE IN X RAY THERAPY.

To the Editor of THE LANCET.

SIR,—Having just returned from Erlangen after a week of study of the methods of deep X ray therapy as practised there, notably in the treatment of malignant disease, it might be interesting to others if I record my personal impressions. In the first place, the X ray therapy devised by Prof. Seitz and Prof. Wintz differs radically from that generally practised in this country. In conjunction with the manufacturers, they have devised an apparatus and tubes capable, with suitable filtration, of giving out, and of sustaining, homogeneous rays—that is to say, rays the absorption of which (and therefore the therapeutic effect) is more or less uniform per centimetre of tissue traversed. They have been able, by the iontoquantimeter, to ascertain the exact proportion of the skin dose that is absorbed at varying centimetre depths. They have demonstrated that there must be a *definite* unit skin dose (U.S.D.) which causes certain *definite* effects, and that there is a *definite* percentage of this U.S.D. (which they designate as 100) which is lethal to the cancer cell, another percentage which causes the death of sarcoma cells, and so on.

The whole process is mathematical and accurate, but to secure results special apparatus is required. The ordinary X ray outfit, however powerful, if

EPSOM COLLEGE: SIR WALTER BUCHANAN SCHOLARSHIP.—The Council will shortly award a Sir Walter Buchanan Scholarship, the value of which is about £33 a year. The rule fixed by the founders of the scholarship is as follows: The Sir Walter Buchanan Scholarship is primarily intended for the sons of deceased or prematurely invalided officers of the Indian Medical Service, or failing any such candidates for the sons of legally qualified medical men of pure British parentage in necessitous circumstances who have practised medicine for at least five years in India. Applications should be sent to the Secretary, Mr. J. B. Lamb, 49, Bedford-square, London, W.C. 1.

was striking. Tall, big, and ruddy, with a kindly expression, he looked, as indeed he was, the incarnation of all that is best in British medicine.

Though for some months his strength had been failing, Dr. Coombs's final illness was brief and painless. He died on Sept. 13th, in his eightieth year, leaving his widow and four children to mourn their loss. His only son is Dr. Carey F. Coombs of Bristol.

JOHN WARD COUSINS, M.D.LOND., F.R.C.S.ENG.,

CONSULTING SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL.

Dr. J. Ward Cousins, whose name is well known to the medical profession both as a general surgeon and as a medical politician, died on Sept. 22nd. The second son of the Rev. T. Cousins, an Independent minister, he was first apprenticed to Dr. E. J. Scott, surgeon to the Royal Portsmouth Hospital, and then in 1853 entered as a medical student at St. Thomas's Hospital, where three years later he gained the Cheselden medal. In the same year he qualified M.R.C.S.Eng. and L.S.A. In 1858 he graduated M.B. at the University of London, taking the M.D. in the following year. A year later he became F.R.C.S.Eng., by examination. After holding a resident appointment at the City of London Hospital for Diseases of the Chest he became attached to the staff of the Royal Portsmouth Hospital in 1863, and to the Portsmouth Eye and Ear Infirmary. From 1895 to 1899 he was a Member of Council of the Royal College of Surgeons of England and their representative on the Central Midwives Board. In the affairs of the British Medical Association Dr. Cousins took a lifelong interest; he was for many years hon. secretary of the Portsmouth division, becoming president of the Central Council, and president of the Association on the occasion of its visit to Portsmouth in 1899. His wide range of interest is reflected in his writings, which include a Review of the Treatment of Stone, the Treatment of Tinnitus Aurium, Ectopic Gestation, and Tuberculous Disease of Joints. A variety of surgical instruments which he invented or improved bear witness to his inventive genius, being rewarded by a British Medical Association prize and by a gold medal at the International Inventions Exhibition. He was on the Commission of the Peace for the borough of Portsmouth. Able surgeon, faithful colleague and good citizen, his place will be hard to fill.

WILLIAM ARTHUR LOXTON, M.B., CH.B. BIRM., F.R.C.S. EDIN.

THE death of Dr. W. A. Loxton took place last week at Budleigh Salterton, where he was on holiday. Dr. Loxton was educated at Birmingham University, where he took the degree of M.B., Ch.B. in 1904, having qualified M.R.C.S. Eng., L.R.C.P. Lond. in 1887. He served as house surgeon to the Queen's Hospital, Birmingham, before specialising in diseases of the skin, which, with venereal diseases, formed his principal interest. He was appointed to the honorary staff of the Birmingham Midland Hospital for Skin and Urinary Diseases in 1890, and for the last three months of his life was the senior member of the staff. He was also medical officer to the Birmingham Venereal Clinic, and the author of several publications dealing with venereal diseases. Dr. Loxton was at one time president of the Midland Medical Society. He leaves a widow and a daughter.

BENJAMIN POPE VIRET, M.B. LOND.

Dr. Benjamin Pope Viret, who died on Sept. 16th at his residence in Horton-lane, Bradford, Yorks, bore the name of his father, a well-known civil servant, and was educated at St. Paul's School and St. Bartholomew's Hospital. He became M.R.C.S. Eng., L.R.C.P. Lond. in 1890, and graduated M.B. Lond. in 1893. After an appointment as house surgeon to the Dorset County Hospital he entered into private practice in the city of Bradford, where he remained for the last 24 years of his life. He was a referee for the Pearl and other insurance companies and one of the factory surgeons in the city. While engaged in his professional duties he contracted an infected wound, which set up septic pneumonia, from which he died with tragic suddenness. A cultured man of wide reading and fond of his profession, Dr. Viret did not seek publicity. He was 54 years of age and leaves a widow and three children.

ROBERT A. FLYNN, F.R.C.P. IREL.,

CAPTAIN, ROYAL ARMY MEDICAL CORPS.

THE death occurred last week of Captain R. A. Flynn who, before the war, was a well-known gynæcologist practising in Dublin. Having taken his medical qualifications in 1887, Flynn served the usual period as Assistant Master in the Rotunda Hospital, and then began practice in Dublin. He was for many years gynæcologist to the Drumcondra Hospital. Early in the war he accepted a commission in the Royal Army Medical Corps and, liking military work, he accepted re-engagement in preference to demobilisation after the armistice. For the past two or three years he was stationed in Dublin. He suffered for some time from heart disease, but his death came as a surprise to his many professional friends in Dublin.

THE LATE DR. T. B. STEDMAN.—Thomas Bernard Stedman, late deputy coroner for N.E. London, who died at his residence, Sheffield, on Sept. 21st., aged 49, had been an honorary demonstrator in toxicology at the University of Leeds and medical officer of health for Leighton Buzzard. Receiving his medical education at University College, London, he qualified M.R.C.S., L.R.C.P., in 1893, and in the same year graduated M.B. with honours at the University of London. He took his M.D. in 1895, and obtained the Diploma in Public Health at Cambridge in 1897. He was a Barrister-at-Law of the Middle Temple.

ROYAL MEDICAL BENEVOLENT FUND.

THE annual report for 1920 of the committee of management of the Royal Medical Benevolent Fund opens with the statement that the diminished purchasing power of money makes it essential that the average amount of the grants, which at present is quite inadequate, should be considerably increased. New subscribers, it is pointed out, are best obtained by a personal canvass, and those interested in the Fund are urged to make its wants more widely known throughout the profession. The total amount received in donations and subscriptions was £3395 4s. 7d., as compared with £2805 3s. 10d. in the preceding year. The total distributed in grants during the year, including Christmas gifts of 30s. to the more urgent cases, was £2708 11s. 1d., of which £216 0s. was provided from the dinner fund account. The total granted the previous year was £2532 1s. Grants were made to 219 cases, and if it were possible to increase the income by £1000 a year it would, with the assistance of the dinner fund, which is kept for special cases and emergencies, be possible to raise the average of the grants by £6. The amounts distributed in annuities during the year totalled £1021 1s. 10d., as against £3897 0s. 5d. in the previous year. The annuitants (who must be over 60 years of age) numbered 178; in December, 1920, it was agreed to increase the amount of 38 of the pensions from £20 to £26.

The Royal Benevolent Medical Fund Guild, which raises subscriptions for the provision of clothes, invalid comforts, and holidays for those who are assisted by the Fund, and also helps in the education of children, is rapidly developing, and the personal interest taken by its members in the applicants is a very valuable form of work. The War Emergency Fund received in January, 1921, a grant of £10,000 from the Committee of the National Relief Fund, to be expended for the benefit of those members of the profession who held commissions and had suffered financial loss in consequence of military service. Grants to the amount of £5926 17s. 6d. were made for this purpose. During the next few years the assistance of young people in the matter of training for a profession will be carried out on a more extensive scale. The committee have already agreed to bear the cost of the education of 25 boys and girls at public schools, and they would welcome applications for such purpose on behalf of any who are eligible for help from the Fund. The expenses of administration, which show a small increase due to the enhanced cost of clerical assistance, of postage, and printing, amount to less than 9 per cent.

London Dermatological Society.—The first meeting of the winter session will be held at 4.30 p.m., on Tuesday, Oct. 18th, at 49, Leicester-square, London, W.C. The opening address on "Skin Eruptions Related to Intestinal Stasis" will be delivered by Sir W. Arbuthnot Lane. All members of the medical profession are invited.

Milk for Mothers and Infants.—At an emergency committee meeting of the National Association for the Prevention of Infant Mortality the following resolution was passed:—

> That this committee is strongly of opinion that the distribution of milk by sanitary authorities is a valuable measure for the protection of infant life. The committee therefore urges the Minister of Health, while doing everything possible to curtail extravagant expenditure, to continue the 50 per cent. grant to those authorities who are complying with Circular 185.

The resolution was based upon the feeling that this relief should be left in the hands of infant welfare centres, since these are able, by means of the expert physicians attached to each, to prescribe the right amount of milk and watch the results on mother and child. No such supervision would be possible if relief in the form of milk-giving were placed in the hands of the guardians, who have not the necessary machinery for such work.

Milk-supply of Dublin.—Last week the Commission on the Industries and Resources of Ireland, appointed in 1919 by Dail Earann, took up the question of the milk-supply of Dublin, and heard a good deal of medical evidence. Dr. M. J. Russell, medical officer of health for Dublin, gave evidence of the difficulties which confront his department in endeavouring to safeguard the milk-supply of the city. In the first place, the corporation has no power to inspect or control sources of supply which lie outside the city. In the next place, the police magistrates are notoriously lax in the penalties they think fit to impose even on the most hardened offenders among milk dealers. Dr. Russell suggested that the penalty for a second offence should be prohibition to trade in future.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, Oct. 4th.

SURGERY: SUB-SECTION OF ORTHOPÆDICS, at 5.30 p.m. (Cases at 5 p.m.)

Cases:—The following will be shown by:—

The President (Mr. Laming Evans): Phocomelia.

Mr. H. A. T. Fairbank: (1) A Case of Subluxation of the Hip-joint of Doubtful Origin. (2) Bilateral Snapping Hips—a further Report on a Case already shown.

Mr. R. C. Elmslie, Mr. W. H. Ogilvie, and Mr. W. Rowley Bristow will also show cases.

Wednesday, Oct. 5th.

HISTORY OF MEDICINE: at 5 p.m.

Statement by the President (Dr. Singer) with regard to the Third International Congress of the History of Medicine to be held in London in 1922.

Approval of the invitation extended to the Congress.

Nomination and election of an Executive Committee, &c. To this meeting all those interested in the matter are cordially invited, whether Fellows of the Society or no.

Thursday, Oct. 6th.

OBSTETRICS AND GYNÆCOLOGY: at 8 p.m.

Specimens:

Mr. Malcolm Donaldson: Malignant Disease of the Cervix Uteri associated with a Malignant Omental Cyst.

Professor Henry Briggs: Green Intraperitoneal Exudate found on the Uterus during Cæsarean Hysterectomy for Uterine Fibroids at Full Term.

Short Communications:

Dr. Barris and Dr. McCurrich: Case of Hæmatoma of the Vulva following Labour.

Dr. Robert A. Hendry (Liverpool): Case of Prolonged Gestation.

Paper:

Dr. Frank A. Nyulasy (introduced by Dr. D. Colquhoun and Mr. Dunhill): Polypoid Decidual Endometritis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Oct. 3rd.—2 p.m., Dr. S. Pinchin: Medical Out-patients. Dr. Simson: Diseases of Women. 2.30 p.m., Mr. T. Gray: Visit to Surgical Wards.

Tuesday.—10 a.m., Mr. Steadman: Dental Department. 11 a.m., Dr. McDougal: Electrical Department. 2 p.m., Dr. Burrell: Medical Out-patients. 2.30 p.m., Mr. Addison: Visit to Surgical Wards.

Wednesday.—10 a.m., Mr. MacDonald: Genito-Urinary Department. 2 p.m., Mr. Addison: Operations. Mr. Gibb: Eye Department. Mr. D. Armour: Visit to Surgical Wards.

Thursday.—2 p.m., Mr. D. Armour: Operations. Mr. MacDonald: Surgical Out-patients.

Friday.—2 p.m., Mr. T. Gray: Surgical Out-patients. 2.30 p.m., Dr. Pritchard: Visit to Medical Wards.

Daily:—10 a.m., Visit of Post-Graduates to Wards. 2 p.m., In-patient, Out-patient Clinics and Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N. Special Intensive Course.

Monday, Oct. 3rd.—4.30 p.m., Clinical Lecture:—Lieut.-Col. W. Byam: The Invalid from the Tropics.

Tuesday.—4.30 p.m., Clinical Lecture:—Dr. A. Giles: Sterility.

Wednesday, 4.30 p.m., Clinical Lecture:—Mr. H. D. Gillies: Plastic Surgery in Civil Cases (lantern).

Thursday.—4.30 p.m., Clinical Lecture:—Sir William Willcox: Diabetes.

Friday.—4.30 p.m., Clinical Consultations on Obscure Cases.

Saturday.—11 a.m., Dr. F. Thomson (at the North-Eastern Fever Hospital, St. Ann's-road, N.): Cases illustrating the Early Diagnosis of the Infectious Fevers.

Daily:—10.30 a.m. and 11.45 a.m., Demonstrations of Clinical and Laboratory Methods. 2 p.m., Demonstrations of Groups of Clinical Cases. 3 p.m.: General Hospital Work. 4.30 p.m., Clinical Lecture (free to Medical Practitioners).

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, Marylebone, W.

Monday, Oct. 3rd.—11 a.m., Dr. J. S. Goodall: Out-patients. 2 p.m., Dr. R. O. Moon: In-patients.

Tuesday.—9.30 a.m., Dr. B. T. Parsons-Smith: Out-patients. 10 a.m., Dr. F. W. Price: In-patients. 2 p.m., Sir Sidney Russell-Wells: Out-patients.

Wednesday.—9.30 a.m., Dr. John Parkinson: Out-patients. 2 p.m., Dr. Moon: Out-patients.

Thursday.—2 p.m., Dr. Moon: In-patients. Dr. Price: Out-patients. 6.30 p.m., Dr. P. Hamill: Out-patients.

Friday.—9.30 a.m., Dr. Parsons-Smith: Out-patients. 2 p.m., Dr. Parkinson: Out-patients.

Saturday.—10.30 a.m., Dr. Hamill: In-patients.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, Oct. 6th.—4 p.m., Lecture:—Dr. Thursfield: Types of Meningitis.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN 49, Leicester-square, W.C.

Thursday, Oct. 6th.—6 p.m., Chesterfield Lecture:—Dr. W. Griffith: The Elementary Lesions of Skin Diseases.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.

Post-Graduate Course on Infant and Child Welfare.

A Course of Twelve Lectures on the Management and Feeding of Infants and Young Children by Dr. E. Pritchard to Qualified Practitioners.

Wednesday, Oct. 5th.—6 p.m., Lecture I.:—Causes of Infant Mortality.

Friday.—6 p.m., Lecture II.:—How to Conduct an Infant Consultation, Examine an Infant and keep Records.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.

Tuesday, Oct. 4th.—4.30 p.m., Lecture:—Mr. J. W. Smith: Duodenal Atony.

Appointments.

Stevens, B. C., M.D., M.S. Durh., D.P.H., has been appointed Medical Officer of Health for Grimsby.

Willoughby, J. F. D., L.R.C.P. Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Acts for the Southwell District of the county of Nottingham.

Vacancies.

For further information refer to the advertisement columns.

Aberystwyth Infirmary and Cardiganshire General Hospital.—Res. H.S. £250.

Benenden, Kent, National Sanatorium.—Asst. M.O. £250.

Bethlem Hospital.—Res. H.P. £25 per quarter.

Birkenhead Borough Hospital.—Sen. H.S. £250.

Bournemouth, Royal Victoria and West Hants Hospital, Poole-road Branch.—Res. M.O. £200.

Bradford Children's Hospital.—H.S. £180.

Bradford Royal Infirmary.—Two H.S.'s. £200.

Bridgwater Hospital.—H.S. £165.

Brighton, Royal Sussex County Hospital.—Cas. H.S. £140. H.S.'s. £140.

Cardiff, City of.—Female Asst. M.O. £550.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Phys. to Out-patients.

Coulsdon, Netherne Mental Hospital.—Third Asst. M.O. £400.

Derby, Derbyshire Royal Infirmary.—Hon. Asst. Surg.

Eastbourne, Princess Alice Hospital.—H.S. £175.

Elizabeth Garrett Anderson Hospital, Euston-road.—Female Asst. S.

Exeter City Mental Hospital.—M.O. £350.

Frimley, Brompton Hospital Sanatorium.—Asst. Res. M.O. £250.

Glasgow Asylum Service.—Asst. M.O. and Pathologist. £275.

"points douloureux" of Valleix. This condition is known in another undoubted nervous disease—alcoholic polyneuritis. In this complaint the nerve trunks are relatively only slightly painful, while the muscles are extremely painful.

But deprived of this argument, the whole fabric of Helweg's proof that the nerve is not the seat of the trouble vanishes. And his only evidence that pathological changes are found in the muscles is that they are tender and their consistence is altered. But this need only indicate that they are *in* a condition of partial contraction. Microscopic examinations or animal experiments were not performed by Helweg. He has therefore in no way proved that sciatica is a muscular disease, and by his theory the explanation of a number of facts becomes difficult. For instance: (1) That the tenderness closely follows the course of the nerve along the back of the leg and its furthest branches as far as the foot. (2) The position of Valleix's points: centrally on the posterior aspect of the thigh; in the middle of the popliteal space; in the middle of the calf; at the side of the leg; behind the external malleolus. (3) The disturbances of sensation and localised paralysis met with now and again in sciatica. (4) The suddenness with which many cases of sciatica arise, and with which, on the other hand, they frequently get well; for example, after a salt water injection. (5) That sciatica is, as a rule, unilateral. Bilateral sciatica is rare, and arouses suspicion of a tumour of the vertebral column, or diabetes. Following Helweg, it might be expected that the disease is often bilateral because the patient involuntarily stands more upon the sound leg than the diseased one, which might lead to hyperfunctioning of the muscles of the normal leg. (6) That sciatica is such a typical disease. According to Helweg, one would expect to find many different forms with pain localised at one time in a certain muscle, at another time in some other muscle dependent upon the work and activity of the patient. The pathogenesis of the disease suggested by Helweg does not satisfactorily explain a number of phenomena. Helweg will not admit the existence of a toxic or infectious sciatica, or of that form due to pressure. But he brings forward no proof that pressure cannot give rise to neuralgia, especially sciatica. It is impossible to support Helweg in his view of the pathology and clinical side of sciatica, but it must be admitted that he has performed a service in emphasising muscular hyperaction as a pathogenetic factor, as it undoubtedly plays a part in many different diseases, and—as we shall see—presumably also contributes to the pathogenesis of a number of cases of sciatica.

Views of Lindstedt.

Folke Lindstedt, a teacher at the Koroline Institute in Stockholm, has published some papers on sciatica[2] in the last few years, in which he supports the following view: Sciatica, in the large majority of cases, is a pure neuralgia, a functional disease without anatomical findings in the nerve. It arises from the presence of painful or merely irritating conditions in the periphery of the nerve which cause pain *radiating* into the whole of the sciatic area in the same way that toothache can produce trigeminal neuralgia. The irritation must have a certain amount of persistence or strength, and the person must have a susceptibility to neuralgia. If the susceptibility, "the neuralgic disposition," is great—in other words, if the individual is markedly neurasthenic—the "irritamentum" need only be trifling.

In an investigation of 100 cases of sciatica Lindstedt claims to have found the irritamentum in 91, as follows: tumours in 3 patients; lesions of the spinal column, 8; salpingitis, 2; appendicitis, 1; chronic arthritis of the hip-joint, 9; acute ditto, 2; fracture of the femur, 2; trauma of the knee-joint, 11 (N.B.—Often many years back); chronic arthritis of the knee-joint, 3; genu valgum, varum or recurvatum (total), 8; trauma of the feet, 5 (N.B.—Often many years ago); flat foot (Insufficientia pedis), 11; polyarthritis, 12; varicose veins, 8; infantile paralysis, 1; constitutional weakness, 3; septic affections, 2. As a rule these diseases do not exert their irritation directly, but through causation of muscle contractures and static abnormalities. On account of these, certain muscles are overtaxed and become painful, and it is these pains which constitute the peripheral "stimulus." He also considers, however, that painful affections in the periphery can directly give rise to referred pain without involving the muscles. The referred pain need not necessarily extend into the whole of the sciatic area, it may be restricted to a single division, but it can also involve neighbouring regions such as the lumbar. In this way Lindstedt explains the frequent association of lumbago and sciatica. He discusses the possibility of muscle contractures directly causing pain by pressure on the nerve trunk, as suggested by Petrén in 1908; but he rather discounts this by assuming that there is not always contracture present.

Comparative Views.

It is clear there is a marked difference between the points of view of Lindstedt and Helweg. A superficial similarity exists in the fact that Lindstedt allows muscular contracture and tenderness to participate in his explanation of sciatic neuralgia. But he entirely scorns the idea that the muscles themselves are the seat of the trouble. On the other hand he is inclined, like Helweg, to look upon the neuritic symptoms, anæsthesia and paresis, as functional and due respectively to exhaustion of the central receptive apparatus and of the muscles. He indicates that Lasègue's symptom may possibly be caused by tightening of the muscles, and does not feel sure that the nerve trunk itself is painful. Lindstedt's view will certainly receive the greater measure of support. The prominence he gives to the neurasthenic element, "the neuralgic disposition," is undoubtedly just; one can also agree with him that many of the pathological lesions he cites as causes of the disease play a part—for instance, the chronic hip and knee-joint affections, spondylitis and flat foot. But he certainly goes too far when he makes trauma of the foot and knee, acquired years ago, responsible for sciatica, or when he sees a causal nexus between appendicitis, salpingitis, varicose veins, polyarthritis, and many other affections occasionally found in a sciatic patient, and sciatica itself. Lindstedt is unable to bring forward any sound evidence of a connexion; the combination can just as well be explained as fortuitous. There is, after all, something forced in this attempt to view all cases of sciatica as secondary. In most cases sciatica is apparently a true disease with a typical course and of limited duration. The pathogenesis championed by Lindstedt is better adapted to chronic conditions with occasional sciatic pains. Moreover, he himself points out that material from the out-patient department might possibly have afforded more cases of genuine sciatica; the above-mentioned investigation deals only with in-patients.

Ljungdahl's Hypothesis.

Ideas of a similar nature are held by Ljungdahl.[3] But *there is a not inconsiderable difference. Ljungdahl only* deals with sciatic pain in spondylitis deformans and osteoarthritis deformans coxæ. He is not out to show that the pain is caused by these maladies, but simply constructs an hypothesis for the way in which they arise. The hypothesis is this: the pain is a reflex phenomenon similar to Mackenzie's viscero-sensory reflex. What gives rise to the reflex is the early destruction in the diseased portion of the bone or cartilage. He regards the conditions as traumata threatening the tissues with destruction or breaking down. The pain is the patient's signal of distress; the simultaneous contractures in the surrounding muscles are similarly the self-defence of the organism, analogous to Mackenzie's viscero-motor reflex. Ljungdahl, therefore, does not think that the muscle contractures and the associated tenderness contribute to cause the pain; in other words, he does not consider that the extent of the contractures and the amount of pain bear a close relationship to one another. Nor are Ljungdahl's views entirely in harmony with the theory of referred pain, since this postulates primary pain which overflows into other channels. Ljungdahl regards every explanation connected with myositis—that is, all inflammatory conditions of the muscles—and the extension of the trouble, perineuritis, as having no foundation, and does not agree that inflammatory infiltration of the muscles could produce nerve tenderness, from pressure. But he passes over the possibility of muscular contracture being able to cause it. He talks about exhaustion myalgia, but does not make use of it in the pathogenesis of sciatica.

General Conclusions.

I will review, in conclusion, what emerges from the above considerations on sciatica, as far as I am able to judge.

Sciatica is a symptom-complex which can arise under the most diverse circumstances. There is certainly a group—perhaps not large, but certainly existent—of neuritic sciaticas. It comprises the following: cases where the nerve fibres themselves are affected; alcoholic and lead neuritis especially localised in the sciatic nerve; the not uncommon sciatic neuritis in diabetes, which can only be cured by an appropriate diet; herpes zoster neuralgia in the sciatic nerve, in which, of course, there is affection of the spinal ganglia—probably a number of cases of influenzal and malarial neuralgia (and neuritis) also belong to this class; lastly, malignant growths in nerves. There is

Medical News.

THE eleventh London Medical Exhibition will be held at the Central Hall, Westminster, from Oct. 3rd to 7th inclusive, open each day from noon to 6 P.M. This exhibition is limited to members of the medical profession, who can obtain cards of admission on application to the Secretary, at 194, Bishopsgate, E.C., or at the Hall during the exhibition week.

SOCIETY OF M.O.H.'S.—The annual dinner will be held at the Café Royal, Régent-street, London, W., on Friday, Oct. 21st, at 7.30 P.M., when Sir A. Mond, Sir Gordon Hewart, Sir Norman Moore, Sir Anthony Bowlby, Sir George Newman, and Sir Philip Magnus, among others, are expected to be present. Ladies are invited, and early application for tickets (price 12s. 6d.) should be made to the Executive Secretary, at 1, Upper Montague-street, London, W.C. 1.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.—The following entrance scholarships have been awarded for the sessions 1921–22:—

University Scholarships of 50 guineas each.—N. F. Adeney, B.A., St. John's College, Cambridge; W. R. H. Pooler, B.A., Downing College, Cambridge. *University Exhibition of 30 guineas*: G. B. Wood Walker, B.A., King's College, Cambridge. *Entrance Scholarships in Natural Science.*—£100: B. W. Goldstone, Haberdashers School and Cheltenham College; £50: M. Odess, School of Mines and Technology, Johannesburg. Palmer Scholarship, £25: E. I. Puddy, Mercers School, Holborn. Epsom College Scholarship (by nomination): G. E. G. Pierce.

AMERICAN DIETETIC ASSOCIATION.—The fourth annual meeting of this Association will be held in Chicago on Oct. 24th, 25th and 26th. Among the papers to be read are: the Newer Ideas on the Dietetic Management of Diabetes and their Working Out in the Hospital, by Dr. R. T. Woodyatt; the Dietary Needs of a Children's Hospital, by Dr. A. L. Daniels; and the Hospital Dietitian, by Miss Marion Peterson. Papers on the dietary customs of various nationalities will be communicated by various observers, and round table discussions will be held on activities in dieto-therapy, laboratory research, and its clinical application. The Secretary of the Association is E. M. Geraghty, 801, S. Wright-street, Champaign, Ill.

MINISTRY OF PENSIONS.—The Minister of Pensions has now taken steps to make more widely known the benefits available to disabled officers and nurses and the relatives of those deceased. With this object a new series of leaflets (officially described as "M.P.O. Leaflets") is being issued, dealing with the following matters: No. 1, general information for disabled officers; No. 2, provision for disabled nurses; No. 3, medical treatment of disabled officers and nurses; No. 4, supply, renewal, and repair of surgical and artificial appliances (other than artificial limbs); No. 5, alternative retired pay; No. 6, pensions and allowances to widows and other relatives of deceased officers; No. 7, supply of artificial limbs (in preparation); No. 8, special grants committee's arrangements for officers and nurses and their dependents. Copies of Nos. 1, 2, 5, and 6 can be obtained on application to the Secretary, Officers' Branch, Ministry of Pensions, Cromwell House Annexe, Millbank, S.W. 1; of Nos. 3, 4, and (later) 7, to the Commissioner of Medical Services at any of the regional offices of the Ministry; and of No. 8 to the Special Grants Committee (Officers), Thorney House, Smith-square, London. S.W. 1.

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.—The annual members' conference will be held on Oct. 6th–8th. On Thursday, Oct. 6th, at 11 A.M., a lecture will be given by Sir James Purves Stewart on "Disseminated Sclerosis" at the Mortimer Hall, 93, Mortimer-street, London, W. 1. At 3 P.M., demonstrations on "The Treatment of Empyema" and "The Tests and Progression of Muscular Work in Heart Cases" will be given by Miss Angove in the Physiological Theatre of Guy's Hospital, London, S.E., and the massage department of this hospital will be visited. At 6 P.M. Dr. Arthur F. Hurst will lecture on "Massage and Exercises in Gastro-Intestinal Disorders," at the Steinway Hall, 15, Lower Seymour-street, London, W. 1. On Friday, Oct. 7th, at 11 A.M., Sir Henry Gauvain will lecture on "The Treatment of Surgical Tuberculosis, with Particular Reference to the Indications for Massage," at the Mortimer Hall. At 3 P.M. Miss Stansfeld will give a lecture-demonstration on "The Importance of Physical Fitness for the Professional Woman," at the same place. At 6 P.M. Dr. J. B. Mennell will lecture on "Passive Movement," at the Steinway Hall. On Saturday, Oct. 8th, at 11 A.M., Dr. H. Crichton Miller will speak on "The Psychological Significance of Rest," at the Mortimer Hall.

LONDON TELEPHONE EXCHANGES.—Transfer from Paddington 1814 to Langham 2567, H. W. Carson; from Paddington 2608 to Langham 2551, C. W. Chapman.

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held at 90, Buckingham Palace-road, London, S.W., on Oct. 12th, at 4 P.M., when a discussion will take place on Plumbing and Sanitation on Board Ship, Sir Henry Tanner presiding.

POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.—The autumn session of the College will commence on Monday, Oct. 10th. Particulars of lectures, clinics, and classes will be found in our medical diary.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.—A meeting will be held at 11, Chandos-street, Cavendish-square, W., on Oct. 21st, at 4.15 P.M., when the subject of Games for Girls will be discussed.

AMALGAMATION OF LONDON HOSPITALS.—The negotiations for the absorption of the Royal Chest Hospital by the Great Northern Central Hospital, Holloway, having come to a successful issue, the committee of the latter institution have been made, by an order of the Charity Commissioners, responsible for the management of the Royal Chest Hospital as from Sept. 6th.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The opening ceremony of the eightieth session of the School of Pharmacy will be held at 17, Bloomsbury-square, W.C. on Wednesday, Oct. 5th, at 3 o'clock. The presentation of the Pereira Medal will take place, and the inaugural sessional address will be delivered by Sir David Prain, F.R.S., director of the Royal Botanic Gardens, Kew.

NATIONAL ASSOCIATION FOR THE PREVENTION OF INFANT MORTALITY.—A course of elementary lectures on infant care, for infant welfare workers, mothers, teachers, &c., will be held at Morley Hall, George-street, Hanover-square, W., on Mondays, 6–7 P.M. from Oct. 3rd to Nov. 7th, and at the lecture hall of the Central Council for Infant and Child Welfare, 117, Piccadilly, on Mondays, 6–7 P.M., from Nov. 14th to Dec. 19th, in preparation for the elementary certificate of the Association.

Y.M.C.A. MEDICAL LECTURES.—A series of popular medical lectures is to be delivered on Mondays (6 to 7 P.M.), Oct. 10th to Dec. 12th, at the Central Y.M.C.A., 186, Aldersgate-street, London, E.C. The lecturers will be Sir James Cantlie, Sir Charters Symonds, Sir James Dundas-Grant, Sir Nestor Tirard, Sir Bruce Bruce-Porter, Prof. W. D. Halliburton, Sir Robert Armstrong-Jones, Sir Frank Colyer, and Sir Sydney Russell-Wells.

BIRMINGHAM GENERAL HOSPITAL.—Owing to the serious financial position of the hospital the board of management recently decided to close two wards, containing 50 beds. This resolution took effect on August 1st, one ward having previously been closed at the Jaffray Hospital, which works in conjunction with the General Hospital and relieves it of many chronic cases. The position is the more serious as Birmingham was already insufficiently provided with hospital beds, and it had been calculated that an additional 1000 beds were required to meet the needs of hospital patients. On August 20th a letter, signed by the Vice-Chancellor and Principal of the University with the Dean of the Medical Faculty, was addressed to the chairman of the board of management, expressing the regret of the Faculty of Medicine at the closure of the two wards. The Faculty is specially concerned in the matter because of the large entry of students since the war. Those responsible for the clinical teaching had drawn up a scheme so that each student might have a proper amount of clinical material allotted to him; this scheme had been prepared with considerable trouble, on the assumption that the full number of beds would be available. The Faculty expresses the hope that the public will realise the seriousness of the position which has been created, and will, by a prompt and liberal support, enable the board of management to reopen these wards at an early date. The chairman of the board, in reply, stated that such a serious course as the closing of beds had been taken only after the most careful consideration, and had, perhaps, been delayed even longer than it should have been in view of the financial situation. The board realise that, owing to the large influx of students, the duties of the Medical Faculty are exceptionally heavy at the present time, and they regret that these difficulties should be added to by the closing of wards. Special efforts have for some time past been made to increase the income of the hospital, and, although these are meeting with a certain measure of success, there is still so large a difference between income and expenditure that the board are quite unable to say when they are likely to be able to reconsider their decision.

"the healthy instinct of reproduction, beautified in the attractive colours of youthful love, in the strong tones of passion, in the delicate tints of spiritual harmony," and have nothing in common with prostitution, "which is offensive because it is an act of violence on the part of the woman over herself, brought about by the pressure of fortuitous and external advantages; in prostitution there is no place either for love or for passion, nor is there any healthy instinct for the production of offspring. It is an act of deliberate calculation merely. Where passion or attraction enters prostitution ceases."

INFLUENZA IN MAURITIUS.

"THE Spanish Influenza in Mauritius" is the title of a brief account of the 1919 epidemic on that island, written by Mr. A. F. Fokeer, a layman who has been at pains to collect and summarise medical opinion concerning the infection and its treatment. Mr. Fokeer claims that up till the cholera epidemic of 1852 Mauritius was one of the healthiest places in the world; increase of population with no corresponding increase of housing facilities, and with defective sanitation, have considerably dimmed its reputation, and the account opens with an indignant denial of the allegation that present conditions are chiefly due to the large Indian section of the community. However that may be, isolated cases of influenza appeared in April, 1919; by May 14th the epidemic had broken out, and in the period from that date till the end of July it carried off 15,000 people—i.e., between 5 and 6 per cent. of the population of the island. There was an almost complete stoppage of trade and public business; the newspapers appeared intermittently, and the railway service was reduced to a minimum. Energetic measures were taken by the Government to combat the epidemic; the civil service and various voluntary organisations rendered valuable aid, but for an interval there were neither sufficient temporary hospitals to house the sick, nor time and materials for proper burial of the dead. Mr. Fokeer worked for a fortnight in a hospital mainly staffed by a Roman Catholic brotherhood, and then fell ill himself. One chapter which is occupied with a discussion on the possibilities of personal survival after death seems hardly relevant to the reader, although the author doubtless found it otherwise. Of more medical interest is the section devoted to the Ayurvedic view of influenza and its treatment.

SAFE CUSTODY OF DRUGS.

CONSIDERABLE publicity has not unnaturally been given in the press to the death of four patients at Powick Mental Asylum through a member of the medical staff of the institution having made up for them and six others glycerine and belladonna instead of glycerine and cascara. The medical man who made the mistake gave a perfectly frank account at the inquest on three patients who died almost immediately, and at a later inquest on a fourth who was thought to be recovering, but who succumbed to pneumonia. He explained what he had done by saying that he never expected that belladonna would be found placed in juxtaposition with castor oil and other drugs of similar harmless character. A verdict of death by misadventure was returned. It may be said in comment that neither a drug such as belladonna nor any other drug for use in a dispensary should be kept in a bottle or other receptacle bearing no inscription or ready means for identifying it without possibility of mistake; and also that insistence on orderly arrangement in accordance with fixed rules would provide a further potent safeguard. With regard to this a woman medical correspondent writes to us to lay emphasis on the necessity for impressing such orderliness upon all who have charge of drugs of any kind, including medicines, lotions, and liniments whether professionally or otherwise. She refers in particular to the giving of instruction in such matters to school children and others in the course of lessons on hygiene. Orderly habits can certainly be taught, particularly where the necessity for them can be pointed out to, and impressed upon, the pupil. In homes as well as in hospitals they should be matters of discipline and routine.

PRESENT-DAY GOLF.

IN a book with this title,[1] by George Duncan and Bernard Darwin, with photographic illustrations by G. W. Beldam, all tastes and handicaps are catered for. The scratch man, we imagine, will give his attention chiefly to the first part, in which Duncan describes and analyses the methods by which famous players achieve their results, and discusses such matters as putting and wrist work, the distribution and transference of weight, and the correct use of the various clubs. All this is rather strong meat, and if we had any hope that our advice would be taken, we should urge the long handicap man to be cautious in practising the principles which Duncan sets forth, for the strong man's diet may well prove fatal to infants and invalids. But there is no one more hopeful than the hopeless duffer, and certainly if the game can ever be learnt from books, it can be from this one. The illustrations to these chapters are numerous and excellent. Particularly fine is one which shows the author's follow through; it is a model of controlled abandon. Mr. Darwin, who is responsible for two-thirds of the volume, writes in his own inimitable way of heroes past and present, famous courses and famous finishes, handicapping, and a host of other things. Particularly delightful is his chapter on children and golf; it could only have been written by one who is richly endowed with the spirit of both. We have no doubt that this book will prove a source of profitable enjoyment to keen golfers who spend the long winter evenings reading, talking, and thinking of their favourite game.

COLOUR EQUATIONS.

AN important method of examining the colour-sense is that of equations of colours, and the white equation is the one usually employed. Two or three colours, for example, spectral red, green, and violet, are mixed until the resultant is indistinguishable from simple white. By means of the Abney apparatus, as modified by Fulton, Mr. F. W. Edridge-Green has recently[1] isolated these colours from the spectrum of a 1000 c.p. "Pointolite" lamp, and then recombined them by means of a lens. The equation obtained after the observer's eyes had been fatigued by light from the red end of the spectrum showed a much lower proportion of green, approximately half the amounts obtained under normal conditions. A variation in the same direction was found also in the colour-blind. The importance of these observations lies in the supposition that red light affects only the hypothetical red sensation, and Mr. Edridge-Green considers them quite inconsistent with the three-sensation theory.

THE BOTTLE-FED BABY.

A SMALL pamphlet[2] written for the Society for the Prevention of Sickness embodies much of the more recent teaching on the artificial feeding of infants, its 22 pages being packed with practical and detailed instruction for mothers. In an introductory note, Dr. Emile Berliner points out that before the introduction of milk pasteurisation one bottle-fed baby out of four died before the end of the first year, and though these figures have been greatly reduced, there is no doubt that if the advice given in these pages were to be more generally followed a still further reduction would be ensured. The first three pages of the pamphlet are devoted to the subject of breast feeding, intervals of three hours being advised from the third day till the end of the eighth month, with six feeds in the 24 hours during the last four months. The author perpetuates the old idea, somewhat discredited of late, that malt liquor is a galactogogue. With regard to the treatment of cow's milk, while pasteurisation is approved of for older children, Dr. Steinberg strongly recommends the scalding or boiling of milk for babies as rendering it more digestible. In this connexion photographs published by Dr. Joseph Brenneman are reproduced, illustrating the appearance of raw whole milk, pasteurised milk, and boiled milk respectively, after 30 minutes to two hours in the stomach, pointing the moral that raw milk is like a solid food in the stomach and unsuited to the baby's powers of digestion. Simple but detailed directions are given for the preparation of the baby's bottle, as also for the use of milk powder, schedules of feeding up to one year old being also appended. The pamphlet has an appreciative foreword by Prof. George M. Kober, Professor of Hygiene and Preventive Medicine at Georgetown University.

THE *Chief Inspector of Factories* announces the following vacant appointment:—Bradford, West (York, West Riding).

THE *Secretary of State for the Home Department* gives notice that he proposes to appoint a Second Medical Referee under the Workmen's Compensation Act, 1906, resident preferably in West Norfolk, for the Attleborough, Aylsham, Downham Market, East Dereham, Fakenham, Holt, King's Lynn, North Walsham, Norwich, Swaffham, Thetford, and Wymondham County Courts, in Circuit No. 32. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than Oct. 19th, 1921.

Births, Marriages, and Deaths.

BIRTHS.

BOOTH.—On Sept. 19th, at Wellington, Madras, the wife of Major E. B. Booth, D.S.O., R.A.M.C., of a daughter.

DODSON.—On Sept. 19th, at the Corner House, Caythorpe, Grantham, the wife of Major Charles S. Dodson, late R.A.M.C., of a son.

DUNLOP.—On Sept. 24th, at Golders Green-road, N.W., the wife of Dr. W. A. L. Dunlop, of a daughter.

HUNOT.—On Sept. 17th, at Victoria-road South, Southsea, the wife of Surgeon-Lieut.-Commander F. C. Hunot, R.N., of a daughter.

MICKLEM.—On Sept. 12th, at King-street, Great Yarmouth, the wife of T. E. Micklem, M.B., of a son.

MARRIAGES.

GOSSET—HUTCHINSON.—On Sept. 6th, at the Parish Church, Ilfracombe, A. Christopher Vidal Gosset, M.R.C.S., L.R.C.P., to Marjorie M. Caldwell, youngest daughter of Mr. and Mrs. Hutchinson, of Ilfracombe.

HERAPATH—BRACEY.—On Sept. 21st, at St. Nicholas Church, Great Yarmouth, Charles Edward Kynaston Herapath, M.C., M.D., to Phyllis Gertrude, eldest daughter of H. J. Bracey, Marine Parade, Great Yarmouth.

READ—SADLER.—On August 4th, Harold Read, M.R.C.S., L.R.C.P., L.D.S., of 17, Welbeck-street, W.1, to Georgina Constance Sadler, of Netherwood, East Molesey.

DEATHS.

LEYTON.—On Sept. 21st, at Great Shelford, Cambridge, Albert Sidney Leyton, M.D., Sc.D., F.R.C.P., D.P.H., aged 52 years.

LOXTON.—On Sept. 20th, at Budleigh Salterton, Devon, Arthur Loxton, M.B., Ch.B., F.R.C.S. Edin., Senior Surgeon to the Birmingham Skin and Urinary Hospital, of Oxford-road, Moseley, and Cornwall-street, Birmingham, the dearly loved husband of Kathleen Loxton. Heart failure while bathing.

STEDMAN.—On Sept. 21st, at Fulwood-road, Sheffield, Thomas Bernard Stedman, M.D. Lond., M.R.C.S., L.R.C.P. Lond., D.P.H. Camb., aged 49 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SCIATICA:

SOME RECENT SCANDINAVIAN INVESTIGATIONS ON ITS PATHOGENESIS

BY DR. HANS JANSEN,

DIRECTOR OF THE DEPARTMENT FOR MASSAGE AND HYDROTHERAPY AT BISPEBJERG HOSPITAL, COPENHAGEN.

OF late years there has been a tendency to look upon the neuralgias as forms of neuritis; that is to say, it is presumed there is in all these diseases an inflammatory condition in the nerve or in its sheath. K. A. Petrén in particular has supported this view in the Scandinavian Text-book of Medicine, 1916. On the other hand, Wertheim Salomonson and Oppenheim continue to regard neuralgia as a purely functional irritation of the nerve without demonstrable anatomical changes. This view is also held with regard to sciatica. Petrén previously explained in a similar way certain cases of sciatica, in which he found myositis (or at any rate spasm) in the deep gluteal muscles, and he thought that this condition alone might possibly cause sciatica by pressure on the sciatic nerve. This muscular origin of sciatica is discussed in Kleen's handbook on massage, and is well known to all masseurs and doctors skilled in that subject.

Helweg in Denmark and Lindstedt and Ljungdahl in Sweden have busied themselves with the subject, but while Lindstedt and Ljungdahl are content with classing sciatica as a pure neuralgia, Helweg goes further, excluding it from the neuralgias and looking upon it as a muscular complaint.

Helweg's Theory: Sciatica a Muscular Disease.

Helweg's point of view is as follows[1]: "Sciatica is a disease of the kinetic system, caused by overwork, and dependent upon disturbance of muscular coördination." Osteo-arthritis deformans coxæ may, for example, be the starting-point. Chronic hip disease leads to more or less contracture or spasm of the local muscles. They perform static work, which is very fatiguing. If the patient continues to get up and do his work, which means that in addition to the static work the muscles have also to perform ordinary (dynamic) work, then the hip muscles get overtired, and this will mean greater demands on the other muscles "of the same synergic group"; that is to say, muscles which take part in the performance of the same function—for example, in the case of walking, the muscles on the posterior aspect of the thigh. By degrees these muscles may also become exhausted and the hyperfunction reach right down the leg. The same thing takes place in spondylitis deformans, where the point of origin is the disease in the vertebral column, which leads to "static function of the erector spinal muscles in order to fix the affected area." Lastly, "unsuitable attitudes assumed during work, or working at an inconvenient rate," can produce the same result, because certain groups of muscles become exhausted with the result that others have to function excessively, and so on. That the individual does not stop in time may be due to pressure of work, effect of alcohol, &c. Helweg considers the overworked muscles become the seat of pathological changes. He points to lactic acid as the offending substance in accordance with an experiment of J. Lindhard, which shows that lactic acid accumulates in the statically functioning muscles. The muscles are tender in all cases, and in the aggregate these tender and painful muscles along the back of the leg—according to Helweg—afford the clinical picture of the disease we call sciatica.

Sensibility of the Nerve Trunk.

There are many important objections to this theory. In the first place Helweg has not brought any incontestable proof that the disease is not situated in the nerve, or at any rate implicates it. His main thesis is this: when we examine the external popliteal nerve, which is the only part of the nerve trunk which can be directly palpated, we find it is not tender. Now this is not quite correct: even if one is satisfied with "stroking" the nerve, as Helweg is, it will often be found more sensitive than a normal nerve. But on the other hand there is nothing at all unusual in the fact that a thick nerve trunk, composed of motor and sensory fibres and surrounded by dense connective tissue is relatively insensitive. As is rightly pointed out by Wertheim Salomonson, it is not the nerve trunk, but its cutaneous branches, which are tender and give rise to the which were to be done daily before the ordinary physical training began. At the end of a month they were placed together and again examined without questions being asked and in such an order that it was not possible to know to which group the recruit belonged. Unfortunately the exigencies of the service at the time caused a loss of 13 recruits from each batch. From the table below it will be seen that the individuals who had had the special respiratory and circulatory training improved considerably more than did those who had no such training. It is interesting to note that in the former the pulse-rate per minute is greatly reduced, the power to hold the breath and the expiratory force increased, and the bodily endurance as shown by the 40 mm. Hg test raised almost to normal. Such is not the case with the other group. The result in regard to vital capacity is interesting as showing the fact that a good midday service meal considerably decreases the vital capacity of certain individuals who were examined shortly after the meal. When examined next day about 11 A.M., it was found that there was reduction of the vital capacity in only one individual. It is also of interest that many of the individuals who had had the special exercises voluntarily offered statements to the effect that their "wind was greatly improved" or "they could now run without getting blown." (Table I.)

---

[1] Joh. Helweg: Ischias. En Klinisk Studie ([illegible] study). Thesis, Copenhagen, 1920.

TABLE I.

Two groups of records with and without special exercises.	Pulse standing per min.	After exercise per min.	Return to normal in secs.	Vital capacity in c.cm.	Expiratory force in mm. Hg.	40 mm. test in secs.
Group A.						
Before training ..	89·3	115	26·4	3906	88	32·5
After training ..	84	107	25	3840	95	33·8
Group B. (Special exercises.)						
Before training ..	95	119	26·6	3673	84·6	33·8
After training ..	79	97	19·1	3837	117	46

As showing some of the best results obtained, the individual results of three recruits on the special exercises are given. (Table II.)

TABLE II.

Three individual recruits.	Records before and after the special exercises.	Pulse standing.	After exercise.	Return to normal.	Vital capacity.	Expiratory force.	Secs. of supporting 40 mm. Hg.
Bo.	Before.	96	120	30	3580	86	22
	After.	84	96	15	3790	128	37
Br.	Before.	108	132	20	3480	90	38
	After.	96	108	15	4000	114	64
Co.	Before.	96	120	40	4080	78	22
	After.	72	96	20	4520	88	47

It is not suggested that an experiment with such small numbers is conclusive, and it is hoped, when the conditions of the service permit, to undertake a similar experiment with a much larger number of subjects.

My friend, Squadron-Leader H. Harvey, R.A.F.M.S., has made extended observations upon subjects during their course at the School of Physical Training. His results show that certain individuals fall away as regards respiratory and circulatory fitness after a strenuous period of training, the individuals themselves being aware of the fact that they are going "stale." Any system of physical training should first and foremost make a man fit as regards the circulatory and respiratory systems, giving him a pulse not unduly quickened by exercise, a high diastolic pressure within physiological limits (80–90 mm. Hg), efficient respiratory capacity, and good expiratory force.

A SYSTEM OF TEN EXERCISES.

I have, therefore, elaborated a system of ten exercises which take about ten minutes daily to perform, based upon the physiological principles already laid down. In devising these exercises I have looked to nature for guidance, incorporating so far as possible, natural movements. The human baby takes about 12 months before it assumes the upright posture. During this time it performs its own system of physical exercises. Observation shows that these consist, at first mainly, of leg movements on the trunk or of trunk movements on the legs; all such movements, however, being directed towards developing the abdominal and back muscles so essential for efficiency in the upright posture. While lying quietly the infant imitates the correct movements of inspiration and expiration (basis of exercise No. 1); when placed on its back the new-born child kicks and performs leg movements on the trunk (basis of exercise No. 4). Later it begins to try to sit up (basis of exercise No. 2), then it begins to try and turn over to get on to its hands and knees (basis of exercise No. 5), performing also in the endeavour various movements on which exercises No. 6–8 are founded. Finally, having assumed the upright posture, it acquires strength of leg and bodily coördination in the upright posture (exercise No. 10). Exercise No. 9 is included especially as an exercise for massage of the abdominal organs. There is also a psychological consideration in the order in which the exercises are arranged. To many people it is a great mental effort to jump straight from bed on a cold morning and start performing physical contortions. These exercises start by inducing the correct movements of respiration while still lying in bed covered by the bed-clothes. In themselves these movements are the waking-up process, but they are followed by two exercises in which the bed-clothes are rolled back to below the waist and then by one in which the bed-clothes are completely removed. Having proceeded thus far, the process of getting up and continuing the exercises becomes considerably less of an effort, since the respiratory and circulatory mechanisms are already working vigorously, and the mind is now thoroughly awake. Especially important is the realisation that these exercises are more or less "go as you please" exercises. Although for exercises 1–8 five times for each is the number laid down, this number need not be attempted at first, especially if the exercises be employed for people who are not in a good condition of health. When employed for such cases also, it is advisable for the subject to get out of bed and perform a number of respiratory and abdominal movements (exercise No. 1) while sitting on the side of the bed before assuming the vertical posture. When a certain degree of proficiency is obtained the number of the exercises is not increased, but the length of time over each respiratory process and movement is increased, all inspirations and expirations being more slowly and forcibly made.

It is sometimes stated that it is harmful to perform exercises with the breath held. There is, so far as I am aware, no real evidence for this statement. The young infant almost invariably performs its first muscular efforts with the breath held and then pants afterwards. It is conceded that it is desirable to teach subjects to acquire rhythmic coördinated breathing and to overcome, in certain circumstances, the tendency reflexly to hold the breath when engaged in acts requiring attention. For example, it is desirable that an airman using his machine-gun at great altitudes should continue to breathe as normally as possible and not to hold his breath in the rarefied atmosphere. But this is different from stating that any physical-training exercise which impedes the breathing is harmful. The absurdity of the position is seen when it is realised that a man who is told not to hold his breath or to impede his breathing (because it is harmful) while he is bending his head backwards and forwards on his trunk, may within a few minutes be practising for a 100 yards race in which the breath is (if possible) held for 10 seconds or more, while most violent muscular effort is performed. In certain sports and games, particularly in Rugby football, boxing, and under-water swimming, much muscular another group in which direct pressure upon the nerve trunk or its roots is just as good an explanation as do referred or reflex phenomena, such as the ordinary sciatic pains of pregnancy, sciatica with benign and circumscribed malignant tumours of the pelvis, deep abscesses, hæmatomata, abundant formation of callus after fracture, &c. So long as it is not disproved that neuralgia can originate in a nerve exposed to abnormal pressure, this pathogenesis cannot be rejected.

Cold can undoubtedly increase the severity of sciatica, and perhaps even cause it to appear; but probably the rationale is that cold induces muscle contracture which gives rise to referred pain, or pain due to pressure. There are also cases in which the theory adopted by Lindstedt is the most probable. Flat foot and similar static abnormalities in the lower extremity can undoubtedly cause sciatica. Here again the route is doubtless via the muscles. Many other painful affections of the leg can also on occasion produce the disease; thus in my student days I learnt that a corn could be the starting-point. Perhaps here also the muscles are interposed in the chain of causation by occasioning a defective way of walking, or certain muscles are strained to avoid the pain. I can well imagine that hyperaction of the flexor muscles of the leg alone could bring on sciatica, the over-worked and tender muscles causing a referred neuralgia of the sciatic region. Lastly, there are the sciatic-like pains often met with in osteoarthritis deformans coxæ and spondylitis deformans—particularly, as Ljungdahl points out, in the early stages. Ljungdahl's view that trauma of the tissues can be a causative factor seems to me interesting, but I do not think one can exclude the possibility of muscle contractures in the lumbar and gluteal regions contributing to the pain. In fact, I cannot dismiss the old-fashioned idea that contractures can produce sciatic pain directly by pressure on the nerve trunk, the pyriformis and gemelli muscles contracting simultaneously.

Sciatica due to Traumatic Lumbago.

There are still very many quite ordinary cases of sciatica which do not fall into the above categories. These are cases consequent upon traumatic lumbago. There is a distinct tendency to discount, or completely neglect, this condition; insurance doctors are particularly afraid of it, because they think patients are only too willing to talk of "overstraining," immediately they get a pain in the loin. But as a matter of fact our back muscles very often run the risk of overstrain. Many people have had the experience at one time or another of lifting something which was distinctly heavier than expected, or have given a sudden energetic jerk to avoid a fall, and have thus straightway acquired lumbago; moreover, in some of the more severe cases many have no doubt noticed a tendency to sciatic pain. I have met with a large number of patients whose sciatica was doubtless only an aggravation or further development of lumbago.

Symptoms.

It only remains to deal with the symptoms. The pain follows the course of the nerve, particularly the cutaneous branches with their sensory fibres; also the branch coming directly from the sacral plexus—namely, the small sciatic nerve. The latter reaches as far as the popliteal space, and it is possibly its end branches which are responsible for hypersensitiveness in this situation. Valleix's points are for the most part caused by the cutaneous branches. On the leg and foot they are the cutaneous branch of the internal popliteal nerve, the external cutaneous, the external saphenous, and the cutaneous branches of the internal plantar nerve. Lasègue's sign can easily be elicited in most cases by stretching the nerve, but it must be admitted it can also be obtained by stretching the contracted hamstring muscles, in the form of referred pain in the nerve. Some people have extremely short ham-string muscles, so that stretching begins much earlier than usual on both sides. Anæsthesia and paralysis—and, presumably, also absence of the Achilles tendon reflex—should probably be taken as a sign of neuritis. Atrophy I consider to be most frequently due to inactivity.

Ordinary uncomplicated sciatica is a benign disease which of itself tends to get well. When it appears to be chronic, it is either because it is secondary to one of the many cited chronic complaints, or because it has produced a kind of traumatic neurosis in the patient. In such a case it can always be dissipated by appropriate suggestion. In treating sciatica the neurasthenic element must always be kept in mind. Bromides are therefore good drugs to administer, and excellent results can be obtained by the most diverse means from the ordinary camphor oil injections to cauterisation of the external ear. Injections of salt water also have a transitory deadening effect. The first part of the treatment should be designed to combat the muscle cramps and contractures. Heat and massage are the sovereign remedies. The massage should be "dispersing," and principally applied to the lumbar and gluteal regions. Friction and similar stimulating manipulation of the nerve is useless. The musculature of the whole extremity, later on in the treatment, will benefit from massage directed against atrophy. And, finally, at the close of treatment of every case of sciatica, remedial gymnastics should be prescribed to revive the natural function and correct the acquired faulty position.

SOVIET RUSSIA AND PROSTITUTION.

THE conclusion of Mme. Alexandra Kollontay's speech[1] to the Russian Communist Party has come to hand and it is disappointing to find no definite indication of policy in regard to checking the spread of venereal disease. This second instalment contains a terrible description of how prostitution has increased under Bolshevist rule. The central organ of the People's Commissariat of Social Welfare organised, under the leadership of Dr. Golman, an Interdepartmental Commission to Combat Prostitution. The Commissariats or Ministries of Justice, Health, Education, Labour, and other public services were also called upon to help. Discussions were held on the causes, especially the economic causes, of prostitution, without reaching agreement as to practical measures to protect the health of the people. The Interdepartmental Commission officially states that, while professional prostitution is not widely developed in Russia, clandestine prostitution prevails everywhere. Thus, before the revolution there were at Petrograd from 6000 to 7000 registered prostitutes and more than 50,000 women were clandestine prostitutes. To-day we are told: "Prostitution is practised by the Soviet office employees, in order to obtain, by the sale of their bodies, boots that go up to the knee; prostitution is resorted to by the mothers of families, working women, peasant women, who are out after flour for their children and sell their bodies to the manager of the rations division in order to obtain from him a full bag of the precious flour. Sometimes the girls in the offices associate with their male superiors, not for manifestly material gain, for rations, shoes, &c., but in the hope of advancement in the office. And there is an additional form of prostitution, 'careerist prostitution,' which is also based in the last analysis on material calculations."

"Deserters from Work."

At first the idea of prosecuting prostitutes was discussed, but the Ministry of Justice and the other authorities concerned agreed that the only crime for which a prostitute could be arrested was that of being a "deserter from work." In that case, however, a lawful and virtuous wife existing in idleness on the means her husband provided was also a deserter from work. The only thing harmful to the interests of the workers, according to Mme. Kollontay, is the substitution of crassly materialistic calculation of gain for a free association of the sexes on the basis of mutual attraction. This is inadmissible, for it destroys the feeling of equality and solidarity between the sexes, yet no sufficient definition could be given to make it punishable by law. It was, therefore, decided that all persons found wandering about the streets should be placed at the disposition of the Commissariat of Social Welfare and thence sent out after inquiry either to the Sections for the Distribution of Labour Power, or to the People's Commissariat of Labour, or to sanatoriums, hospitals, &c.; and only after evidence of malicious intent to desert from work would the individual be condemned to forced labour, but there is no special culpability attached to prostitutes. No details are given as to the measures taken to decide whether they should be sent to a hospital; we are only told prostitutes must not be separated from or treated differently than other deserters from work. Indeed, all the reports deal with the difficulty of defining prostitution as a crime and of excluding the man from punishment. If the crime consists of the purchase and sale of caresses then the husband of a woman who married him for his money should also be punished!

Remedies.

In spite of all these obstacles, there is a general agreement that if all women had work to do and were sufficiently paid for their work, the principal cause of prostitution would be removed. Consequently the Soviet has adopted a law that the earnings of working men and working women shall be equal. Unfortunately, the majority of women are unskilled workers and are generally insufficiently paid. Better education, especially technical education, better housing, the special teaching in schools of history of the relationship of the sexes on a rigidly scientific basis, are therefore advocated as remedial measures.

Such are the principal points Mme. Kollontay has brought out, based on official reports to the Soviet Government. To her mind, the realisation of the proposals made will tend to do away with the old form of family life and of prostitution. There must be no material calculations in the conjugal relations of the future. They must arise from was at the time that most of this work was done, and particularly to Sir Walter Fletcher for the interest he has shown in the progress of this investigation. My thanks are also due to Lieut.-Colonel A. P. Bowdler, Squadron-Leader E. G. Clarke, and particularly to Flight-Lieut. G. S. Marshall, for help in the preparation of these lectures. Finally, I wish to acknowledge the helpful consideration I have always received from my brother officers of the Royal Air Force, both past and present, and to express my admiration for the courage, skill, and bodily endurance which they so persistently displayed throughout the late war.

Hunterian Lecture

ON

MUCOCELE AND PYOCELE OF THE NASAL ACCESSORY SINUSES.

Delivered before the Royal College of Surgeons of England

BY WALTER G. HOWARTH, M.A., M.B. CAMB., F.R.C.S. ENG.,

SURGEON IN CHARGE OF THE THROAT AND NOSE DEPARTMENT, ST. THOMAS'S HOSPITAL.

INSTANCES of the condition with which I propose to deal have been recorded from time to time under various designations, but only within recent years has an attempt been made to systematise our knowledge of the subject and to give it its proper place as an explicable surgical occurrence. Logan Turner in this country, and Gerber in Germany, were chiefly responsible for elucidating the condition and placing it upon a scientific basis, and it is only the comparative neglect of their work that has impressed upon me the advisability of reconsidering the subject in the light of recent knowledge and experience.

MORBID ANATOMY.

By the term mucocele of a sinus is meant the accumulation and retention within it of a mucous secretion owing to obstruction of its outlet with thinning and possible distension of one or more of the walls of the sinus. When the contents of the cavity are purulent in character the condition is referred to as a suppurating mucocele or pyocele.

The occurrence of mucoceles is not by any means uncommon, and records are to be found of a considerable number of cases, but often the true condition does not seem to have been appreciated; for instance, many cases recorded as bone cysts in the region of the orbit or accessory sinuses would appear to have been true mucoceles. Any of the accessory sinuses may be affected, but I have not met with a case in which the sphenoidal sinus was affected, and it is difficult to find satisfactorily recorded cases. I have not met with a case of mucocele of the maxillary antrum in my own practice, and a study of recorded cases leaves some doubt in the mind as to whether dentigerous or other cysts connected with the teeth had not obliterated the antrum and been mistaken for it; but the occurrence of mucocele of either cavity, though apparently extremely rare, is of course possible.

My own cases, which are 14 in number, have all been connected with the frontal sinus and the anterior part of the ethmoid labyrinth; other recorded cases also seem to show that this may be regarded as by far the commonest situation. In the ethmoid group of my series I do not include those cases where an abnormal air cell in the anterior end of the middle turbinate has become distended by retained mucus and given rise to purely intranasal manifestations. It is true that the middle turbinate is merely a folded-over portion of the ethmoid labyrinth, occasionally containing an accessory air cell the ostium of which may get blocked, but these cases (of which I have seen three) should, I think, be placed in a separate category.

When a mucocele of the frontal sinus occurs the increasing pressure of retained fluid makes itself felt on the bony walls of the sinus, and the thinnest wall, as would naturally be expected, most usually gives way. The inferior wall of the frontal sinus is the thinnest; it is most usual to find a swelling appearing in the roof of the orbit, either in the region just behind the trochlear fossa or somewhat external to it. Any of the walls, however, may be affected; in three of my cases the anterior wall was absorbed, whilst in three others the posterior wall was absorbed and a considerable area of the dura mater consequently exposed. Occasionally more than one wall may be involved; I have one case in which the floor and anterior wall of the right frontal sinus and the anterior wall of the left frontal sinus were involved, the partition between the two sinuses being absent or having been absorbed.

In the ethmoid labyrinth such a varied anatomical formation is met with that it is not easy to say which wall is most commonly affected. Usually the ethmoid is made up of ten or a dozen cells, and when a mucocele arises in this type of labyrinth the partitions between the cells are the first to disappear owing to pressure atrophy and the complicated labyrinth thus converted into one large cavity before the anterior wall shows any sign of absorption. Occasionally ethmoids are met with which normally consist of two or three large cells only, but it would appear that this type of ethmoid is not so likely to be affected.

CLINICAL FEATURES.

The main clinical features of both frontal and ethmoidal mucoceles are orbital in character, so that cases very often come under the notice of the ophthalmic surgeon in the first instance. A swelling is noticed at the inner and upper angle of the orbit. This may feel hard and bony, or the bone may be so thinned that it gives a parchment-like sensation to the touch; in other cases the swelling is definitely elastic or fluctuating, a portion of the bony wall having been absorbed. When this occurs the edges of the gap in the bone can usually be felt, and it is sometimes observed that the bone in this situation is thicker than normal from a deposit of new bone.

There is no tenderness or pain on manipulation, and the skin is unaltered in appearance and freely moveable over the swelling. Pressure on the swelling does not alter its size. The swelling may remain practically stationary for years, but usually when the bone has been absorbed the condition progresses more rapidly and symptoms of pressure on the orbital contents begin to appear. The eyeball is usually displaced downwards and outwards, sometimes forwards as well; the latter occurrence taking place when the mucocele has pushed through the floor of the frontal sinus or the os planum of the ethmoid somewhat farther back in the orbit than usual. As the globe of the eye is displaced diplopia may appear, the images usually being seen one above the other. In some cases a high degree of displacement may occur without any diplopia, whilst in other cases it is one of the earliest signs. The movements of the eyeball are not usually affected.

When the mucocele is purely ethmoidal the swelling may be somewhat lower down, and as it pushes forward may involve the lacrymal apparatus. This may lead to mistakes in diagnosis and a wrong form of treatment. In three of my cases this occurred. I will mention one as an instance. A boy of 12 was playing football at school and received a severe blow in the left eye from another boy's elbow. An extensive black eye resulted which got better in 10 days. Four months later a swelling appeared in the region of the lacrymal sac; in a few weeks' time this was incised and some clear fluid evacuated. He came home and a month later an operation for removal of the lacrymal sac was decided upon and undertaken. The swelling reappeared and five weeks later a second

The Milroy Lectures
ON
RESPIRATORY EFFICIENCY IN RELATION TO HEALTH AND DISEASE.

Delivered before the Royal College of Physicians of London

BY MARTIN FLACK, C.B.E., M.B., B.CH. OXON.,
WING COMMANDER, ROYAL AIR FORCE MEDICAL SERVICE.

LECTURE III.*

In my last lecture I endeavoured to show that flying strain, in its physical aspect—i.e., apart from the mental aspect—is characterised in many cases by *a diminution of the* vital capacity, a loss of expiratory tone, and an instability of the medullary centres—conditions which frequently lead to signs of cardiovascular insufficiency and general nervous instability. Such a bodily condition is not confined to airmen, but may frequently be found in those who have never taken part in flying. It is a condition especially characteristic of bodily inefficiency and of lack of bodily endurance; it may occur in those who have led sedentary lives or who have been debilitated by disease. For bodily efficiency I have put forward for consideration certain points which may be summarised as follows:—

1. Efficient inspiration is necessary for the proper distension of the lung in all its parts. Diaphragmatic breathing is particularly important, otherwise the apex of the lung is not adequately expanded and becomes particularly liable to attack by tuberculosis. By virtue of lack of exercise, trade occupations, mode of clothing, &c., the inspiration of many people of *the present day is defective and of wrong character,* which may help to account for the relatively large amount of tuberculosis of the lung found in town dwellers during the taking of the war physical census.

2. For efficient respiratory interchange of gases *under circumstances demanding the full respiratory* ventilation capacity it is important that the residual air left in the lungs at the end of deep expiration be as near the physiological minimum as possible. This is brought about by active expiration, the contraction *of the abdominal muscles being the most important.* Fit individuals are possessed of good abdominal tone. When such abdominal tone is lacking the vital capacity of the individual falls away, the residual air increases in amount, the ventilation capacity of each breath is *diminished, and the individual becomes easily breathless,* panting to ensure sufficient ventilation instead of breathing deeply.

With this increase in the residual air there is a tendency, *owing* to the condition of slight anoxæmia *induced, for the respiratory* and other bulbar centres to become more excitable, a condition which, in many cases, reflects an increased irritability *of the whole* nervous system. This condition is found particularly in neurasthenia due to stress, and it is possible that this respiratory defect may in some cases be actually the exciting cause of the nervous condition.

3. By virtue of the effect of gravity *the assumption* of the upright posture in man has thrown stress upon the circulatory mechanism. *One of the chief adjuncts* to the heart in combating this stress is efficient respiration. During inspiration the downward plunge *of the diaphragm, during expiration* the contraction of the muscles of the abdominal wall, play a great part in the forcing of blood onwards *from the venous* reservoir towards the heart. The tone of the abdominal muscles is particularly important; when this is lost blood tends to collect in the abdominal vessels and the diastolic pressure in the arteries to fall. It is this condition which probably *accounts for the large* percentage of cases of venous varix found among the general population during the war physical census.

4. Efficient respiratory movements are necessary *for the* preservation of the muscular tone of the alimentary tract. Deficient *respiration is* indirectly a cause of constipation and its attendant ills. The *deep respirations* induced by exercise massage the intestines and serve to combat the tendency to constipation which arises from a sedentary life or occupation. In this connexion good tone *of the belt* of abdominal musculature is also of particular importance.

NECESSITY OF SIMPLE EXERCISES FOR SEDENTARY WORKERS.

It will be seen that in addition to attaching importance to efficient respiratory movements considerable stress is laid upon the disadvantage of the upright posture in man. The evolution of the upright posture was gradual, but it was characterised by much bodily activity, by which the whole belt of abdominal musculature was efficiently developed. To-day, however, after a period of bodily activity *in infancy* during which the upright posture is gradually assumed, and *after a* childhood *for the* most part fairly active, man does not take, either on account of the nature of his employment or through lack of opportunity, the exercise necessary to maintain the tone of the abdominal musculature and thus preserve efficient respiration and *circulation.* Hence bodily inefficiency develops as was shown by the *figures* of the war physical census; this is particularly the case when the days of childhood and childish activity are passed and the struggle for *life* under modern conditions begins. There is a marked deterioration in efficiency between the years of 18 *and 23, which is particularly marked in those* whose occupations do not lend themselves to the expenditure of great physical energy. It is obvious that if man is to continue to be fit physically and to preserve bodily endurance, efficient respiration and circulation must be maintained. One of the *most urgent needs of the moment* is some set of simple exercises which will so maintain the efficiency of the individual that he will remain fit for the continuous sedentary life which is the lot of so many people at the present day, and also preserve such a state of bodily efficiency as will allow of indulgence *in occasional* exercise without undue *fatigue of the respiratory and circulatory mechanisms.* At present it frequently happens that when exercise is taken by a person leading a sedentary life there is a failure of such mechanisms, with the result that the exercise induces profound *lassitude and* does more *harm than good.*

ILL-EFFECTS OF INDISCRIMINATE PHYSICAL TRAINING.

It is a common experience that as the result of a course of *physical training in recruits* certain individuals are in no way benefited but rather deteriorate, and have to be sent to the medical officer for his opinion as to their efficiency. There is no doubt that this is because the exercises employed in most systems *of physical training are not* devoted, in the first place, to building up respiratory and circulatory efficiency. Under ordinary circumstances attention is devoted to general muscular development and accurate muscular coördination particularly of the limbs. *In most systems of physical* training it is a matter of good fortune rather than of foresight that in the majority of *individuals respiratory and* circulatory efficiency are developed at the same time. In the individuals who break down the respiratory and circulatory mechanisms are not equal *to the stress* imposed upon them by the system of training. If in the first place *attention* were directed to the attainment of respiratory and circulatory efficiency, such *individuals* with graduated *training* would *not* fail. This can be seen from the results obtained *upon a* batch of what might almost be termed "C3" recruits. *For the* experiment a batch of 50 such recruits was taken. They were tested by certain of the physical efficiency *tests and* divided into two groups—man for man of relatively equal efficiency. One batch was placed upon physical training without special circulatory and respiratory exercises, the other upon a few special circulatory and respiratory exercises picture is markedly altered. Such occurrences do arise, as the ostium frontale and the ostium ethmoidale, though closed enough to bring about the retention of the contents of the sinus, cannot always prevent the spread of any infective process from the nose. I have only one instance in my series of such an occurrence.

---

* Lecture I. was published in THE LANCET of Sept. 17th and Lecture II. appeared on Sept. 24th and Oct. 1st.

A soldier in the Irish Guards had noticed for many years before the war a swelling in the situation that we regard as typical. He had not had any inconvenience until 1916, when the swelling became larger and his eye was displaced outwards for nearly half an inch. He was sent home to the depôt; some weeks afterwards, when he had a severe cold, he complained of tenderness of the swelling, with some redness of the skin. It was thought to be a lacrymal abscess, and incised, but the ophthalmic specialist was considerably surprised and disconcerted to find that his probe went backwards through the swelling for a distance of nearly three inches. The patient then came under my care and a radical operation revealed a large pyocele that had converted the whole ethmoidal labyrinth into one large cavity. No doubt, this had become infected from the nose and given rise to the acute symptoms.

Cystic dilatation of the lacrymal sac may be confused with ethmoidal mucocele, but in the former condition firm pressure will usually express some of the fluid through the nasal duct into the nose or through the punctum lacrymale into the inner canthus.

Much more difficulty is presented by tumours of the frontal sinus and of the orbit, more especially osteomata and fibro-sarcoma. I have been able to find records of nearly 200 cases of osteoma in the literature. They often grow from the under aspect of the supraorbital margin and push forwards more externally in the orbit than the mucocele. Their solidity compared with the comparative compressibility of the mucocele is a diagnostic point, whilst X ray examination may show the tumour to be very dense. My experience is that X ray examinations in mucoceles are of little if any help in diagnosis.

Osteomata of the frontal sinus may not be so obvious as those of the orbit and may even give rise to acute symptoms; a case was recorded a year or two ago in which a Bavarian soldier went sick with headache, rise of temperature, and swelling of the left upper lid. At the operation a large osteoma was found to be occupying the whole of the left frontal sinus and ethmoid labyrinth.

Malignant tumours usually present less difficulty, although several cases recorded as mucoceles turned out to be malignant growths. Dermoid cysts usually occur at the outer canthus, but I had a case a few years ago of a boy of 10 in which one was present at the right inner canthus. There was, however, no displacement of the eye. Meningoceles have also been described as occurring in this situation, whilst suppurating sebaceous cysts have occasionally caused difficulties in diagnosis.

Duration.—It is difficult to say how long the condition has lasted in any individual unless the occurrence of an accident fixes the probable date of onset. From a study of recorded cases one gets the impression that a large number are of many years' standing; cases are mentioned where 20 years has been given as the probable duration, whilst in others a few weeks is regarded as the probable time.

In my series the group of five traumatic cases gives an idea, in them at least, of the time elapsing between the accident and the first onset of symptoms or of external swelling. In one case of a man who ran into the edge of a heavy oak door and sustained a severe black eye an external swelling appeared in the typical situation about a year afterwards, but caused him no trouble, and it was not until seven years after that that the swelling got larger and he began to notice occasional diplopia and so came under my observation. Of the other traumatic cases three years was the interval between a blow from a piece of shell and the noticing of the external swelling.

In the other three about four months was the time given. In one of these, however, that of the Air Force officer, whom I have mentioned previously, the symptoms were simply watering of the eye, and he went on flying for another year. Very little useful information results from an examination of the other cases, and as there is nothing to date the onset, one seldom gets a history of more than six or eight months.

Age.—The age of the patient is not of much importance, but in this connexion I should like to point out the fallacy of drawing deductions from a small series of cases like mine. Of the non-traumatic cases the oldest was 85 and the youngest 41, whilst the average of the others was over 60, so that one might be inclined to say that the condition was more prone to occur in elderly people. From Logan Turner's series of 10 cases, however, the impression that one would form would be that the affection was one of early adult life. Thus, in this instance, the two series of cases are a useful corrective to each other.

Similarly, as regards the *sinus affected*, my cases show 10 cases where the frontal sinus was affected, 2 where the frontal sinus and the ethmoid were involved, and only 3 purely ethmoidal cases, whereas, a review of recorded cases leads one to the belief that purely ethmoidal cases are much the more common. The lining membrane of mucoceles has been investigated by Onodi and other observers, and detailed accounts published of the microscopical appearances. These serve to show that changes of a chronic inflammatory nature are present both in the lining membrane and in the underlying bone, the latter undergoing erosion and absorption. Where the bone was in process of erosion, large bone cells of the nature of osteoclasts were seen.

Contents of the cavity vary very much in the cases. It is most usual to find it filled with a thick glairy opalescent and almost gelatinous fluid, but the colour and consistence may vary considerably. In those cases where an infection had probably occurred at some time the pus was usually thick and yellow. In all my cases where cultures were made from pus the latter was found to be sterile.

TREATMENT.

Treatment should, I think, consist in exploration of the swelling through an external incision, and then establishment of free intranasal drainage.

The usual eyebrow incision is made, the periosteum with the pulley of the superior oblique is stripped up, and the orbital contents retracted outwards. One can then estimate the extent of the condition and plan the future steps of the operation after the thin bony wall in the upper and inner angle has been removed and the contents of the mucocele evacuated. As much of the bony floor of the sinus as is thought advisable should be removed and a large opening made through the lateral mass of the ethmoid into the nose. The lining membrane of the cavity should not be disturbed except where it has been removed with the bony wall. A large rubber drainage-tube should be passed from the sinus into the nose and sewn to the ala. The external incision should be completely sutured. The drainage-tube may be left in the nose for ten days. If it gets blocked a probe should be passed up it and after the third day some warm lotion may occasionally be syringed up it. No further treatment is required. By making a very large opening into the nose and by removing the floor of the mucocele one practically makes the mucocele part of the roof of the nose. The fact that a considerable area of dura mater may be exposed posteriorly is of no moment, as the rest of the dura is already shut off and the exposed portion considerably thickened.

MANCHESTER ROYAL INFIRMARY.—The post-graduate lectures and demonstrations on medical, surgical, and special subjects given by the honorary staff were resumed this year on Tuesday, Oct. 4th, when Mr. J. W. Smith lectured on Duodenal Atony. Lectures will be held each week (with the exception of Tuesdays, Dec. 27th, Jan. 3rd, April 18th) till May 2nd, 1922, and will be announced in our Medical Diary.

effort is performed with the breath held, and experience has shown that such individuals make particularly *efficient fliers in the rare air of high altitudes.* In my opinion it is decidedly beneficial for an individual to accustom himself to the performance of muscular work with the breath held; he is then more likely to remain efficient in times of physical stress.

As supporting in some measure my views in regard to physical exercises I quote from an article by the late Sir Hermann Weber, written at the age of 83, in regard to his method of using exercise for the prolongation of life.

"I have mostly commenced with moderately deep inspirations and expirations, continued during three to five minutes once or twice a day, and have gradually increased the exercises to ten minutes or one-quarter of an hour. The depth of each inspiration and expiration and the duration of holding the breath are likewise to be only gradually increased. At the beginning one-quarter of a minute for every inspiration or expiration ought to be sufficient. If this is well borne, each act may gradually be prolonged in duration so that in the majority of cases each inspiration and each expiration may be brought up to a minute. All the movements are to be made slowly, not rapidly. I usually advise to inspire in an upright position, with raised arms and closed mouth, to bend down the body during the expiration so that the fingers touch the ground or the toes. By degrees, one can do several up-and-down movements during every inspiration and bend and raise the body several times during the expiration. By this alternate bending and raising of the body we can gently strengthen the lumbar muscles, and through this successfully combat the tendency to lumbago.

"Another useful combination with the respiratory exercises is the turning of the body around the axis of the spinal column alternately, with deep inspirations from left to right and with expirations from right to left, the arms being half raised. By this movement we bring into action some of the muscles of the spine, which are apt to be only imperfectly used by most persons in advanced years, and the stiffness of the neck and spine and the tendency to stooping so common in old persons can be to some degree corrected by this kind of movement. If commenced in good time and practised regularly and thoroughly, swinging the arms around the shoulder-joint is likewise useful, and other combinations with muscle and joint movements will occur, but they should have accustomed themselves to these respiratory movements. The latter ought always to have our principal attention since to them the beneficial effect on the heart and the lungs is mainly due. In addition to the influence on the circulation, the respiratory movements keep up the nutrition and efficiency of the lungs, which undergo in old age a kind of atrophy. The walls of the smallest divisions and air-cells become thinner, and a kind of senile emphysema is developed which by this exercise is to some degree prevented. Another important influence consists in maintaining the elasticity of the chest walls, which are apt to become stiff in old age and thus to interfere with free movements of the lungs and pleura. If, for some reason, the erect position should be inconvenient, respiratory movements can be made also in the horizontal and sitting positions."

In addition to these exercises, taken regularly every morning, Sir Hermann Weber advised a walk lasting from one-half to three hours, part to be taken in the morning and part later in the day, and once a week he recommended a day or more prolonged exercise, and a holiday once or twice a year spent in a walking or climbing tour of three or four weeks.

DEMONSTRATION.

I will now ask the instructor present to demonstrate the ten exercises, directions for which I have laid down as follows. It is to be especially noted that in all these exercises it is of great importance that the process of inspiration is initiated by the contraction of the diaphragm, protruding the "pit" of the abdomen together with a movement of the lower ribs, full inspiration being attained by a wave-like movement spreading from the lower ribs to the upper part of the chest. On no account must the upper part of the chest be expanded first. Expiration is accomplished by the contraction of the muscles of the abdomen and of the lower part of the chest.

Physical Efficiency Exercises.

In Bed.

1. (*a*) Lying flat, inhale to the fullest extent, at the same time raising the hands above the head in a natural "stretching" motion. (*b*) Exhale to the utmost extent, using the abdominal muscles forcibly to press out as much air as possible from the lungs, at the same time carrying the arms to the sides. Repeat five times.

2. Using the weight of the bedclothes turned down to the hips as a means of keeping the legs down, raise the body from the hips and bend forward as far as possible, at the same time breathing out forcibly to the fullest extent, then slowly return to the lying posture, inhaling deeply meanwhile. Repeat five times.

3. (*a*) Using the bedclothes as before, from the lying position raise the trunk, with the hands by the sides, through an angle of 45°, then twist round the trunk upon the hips, keeping the legs flat and endeavour to make the forehead touch the bed, meanwhile exhaling forcibly as far as possible. (*b*) By a reverse movement assume the lying position, inhaling deeply meanwhile. Repeat five times to right and left sides.

4. (*a*) From the lying position, flat on the bed, with the hands clasped behind the head, raise the legs from the hips, carrying them as far over the head as possible, inhaling as deeply as possible meanwhile. (*b*) Lower the legs slowly to the fullest extent, meanwhile exhaling deeply and forcibly. Repeat five times.

Out of Bed.

5. (*a*) By a kind of "stretching" movement raise the arms slowly and strongly forward and upward, then lower them sideways until they are in line with the shoulders which are well thrown back, meanwhile inhaling to the fullest extent. Brace up the muscles of the abdomen and all accessory muscles of inspiration. (*b*) Keeping the body as upright as possible, carry the arms forward until they overlap and hold sides of trunk; expire meanwhile to the utmost extent, working specially the lower chest and abdominal muscles. When in the position of full expiration brace up all muscles of lower chest and abdominal wall. Repeat five times.

6. (*a*) With the feet about 18 in. apart † (or other comfortable distance) carry the arms forward, upward, and backward, inhaling meanwhile to the fullest extent. (*b*) Bend trunk forward and full downward, carrying the arms between the legs to touch the ground with the fingers as far as possible behind the feet, meanwhile exhaling to the fullest extent. Repeat five times.

7. With the feet about 18 in. apart † and arms raised sideways and in line with the shoulders, bend the trunk to the left (right) until the left (right) hand touches or nearly touches the ground, keeping legs straight, meanwhile breathing naturally or holding the breath. Repeat five times to each side.

8. (*a*) With the feet about 18 in. apart † carry the arms forward, upward, and backward, inhaling meanwhile to the fullest extent. (*b*) Turn and at the same time bend the trunk to the left (right), and touch the ground on the outside of the left (right) foot, expiring meanwhile to the fullest extent. (*c*) Stretch trunk upward to upright position, inhaling meanwhile to full extent. Repeat five times to each side.

9. Inhale as fully as possible, then exhale sharply to the fullest extent, and, with the chest and abdominal wall held in position of expiration, work all the abdominal muscles, alternately forcibly contracting and relaxing. Repeat two or three times.

10. Stationary running (often known as the 100 up); shadow skipping; shadow boxing; rhythmic balancing exercises; jumping or any other form of exercise preferred by the subject, until out of breath.

The exercises may be followed by a tepid or cold bath or a rub down with a hard towel wetted with warm or cold water according to the taste of the individual.

In my experience these exercises have given good results; as I have already stated, I believe that they will be found useful in preserving the physical efficiency of those engaged in sedentary occupations and will enable them to indulge in open-air exercise without undue fatigue. They are in no way designed to supplant recreational exercise nor to replace more elaborate systems of physical training. In regard to the latter, it is believed that they will give the correct circulatory and respiratory efficiency which at present may or may not be obtained.

In conclusion, I wish also to thank my friends, Sir Arthur Keith and Dr. Leonard Hill, for the great help and encouragement they have always given me both in connexion with the present work and also in the past. I also wish to place on record my thanks to the Medical Research Council, in whose employ I

---

† These distances can be gradually decreased as, [illegible] is attained.

been a consequence of under nutrition. As the former comparison was adopted in the previous investigation it has been adhered to in the present paper (Table II.).

TABLE II.—*Average Height and Weight of Viennese Children at Different Ages, compared with British Anthropometric Standard Average.*

Middle-class, Town, Sexes Combined.

(A) = Per cent. under Anthropometric Average.

Age in years.	No. of children.	Weight.		No. of children.	Height.	
		Pounds.	(A)		Inches.	(A)
1–2 ..	6	18·8	8·7	—	—	—
2–3 ..	10	20·5	27·3	9	26·2	20·8
3–4 ..	14	26·4	19·1	14	33·1	9·4
4–5 ..	8	29·5	18·8	8	33·4	12·9
5–6 ..	9	33·7	14·1	9	37·5	7·8
6–7 ..	5	34·8	19·2	5	38·1	12·4
7–8 ..	9	41·4	14·7	9	40·8	9·6
8–9 ..	15	45·2	15·3	14	45·6	2·7
9–10 ..	5	49·6	16·2	5	48·1	2·8
10–11 ..	8	54·8	15·2	8	49·8	3·1
11–12 ..	5	62·4	11·1	5	51·7	1·1
12–13 ..	4	58·5	23·3	4	52·4	4·9
13–14 ..	2	72·3	17·2	2	55·5	3·8

It will be seen from this and from Table VI. that under 2 years of age the nutrition of the children of the middle-class families as indicated by the percentages of weight under the Anthropometric Standard is better than that of the labouring classes—8·7 to 14·8 below. It is also slightly better between 3 and 4 years—22 against 26·5. From 4 to 9 it becomes worse —16·0 to 13·2, and from 10 to 14 it is even more distinctly worse—21·5 to 15·5.

Condition of Families in the Country.

The same accuracy of results cannot be claimed for the studies of the rural families as for those in town, because it was impossible to visit them every day, and the statement of the mother as to the amount of food consumed had to be accepted in many instances. The families visited live within a radius of 45 kilometres of Vienna. The country is one of hills covered with woods of every description. Most of the families live in small villages or in little shepherds' huts right away up in the hills. The houses are mostly small, and in many cases the animals live with the family. In the villages the floors of the houses are mostly below the ground level. The children are out a great deal, both in summer and winter. The families were not selected. The names were given by the nurses of the welfare centres as children who did not attend there. They were not families who had received rations from the Friends' Relief Mission, though those who attended school received a meal from the American Relief Administration. This is allowed for in our tables.

The condition of these families varied greatly, some being fairly well-to-do, some being very poor, some depending entirely upon food purchased, others having some produce from their land. In many cases the food-supply varied greatly from week to week and at different seasons. Many had garden produce and goats' milk and butter in summer, but these were not available in March when the studies were made. Probably in some cases all the food consumed has not been noted, but it is of interest that the average energy value of the diets is slightly higher than that of the urban working classes, that the average protein content is rather higher, and that the fat content is very markedly higher on account of the greater use of milk and butter (Table III.).

Family 17 is described as living mainly on bread made at home with water and as keeping poultry. Family 39 use home-made butter which accounts for the high intake of fat. About 40 it is noted that the diet varies greatly from week to week and that during some weeks they are starving. During the week of study they were having vegetables, beans, fish, bread, and flour. The data as regards two families living in the hills and of the family of a carter are so imperfect that they have been excluded.

Nature of Food.

The character of the food differed considerably in the two groups, as shown in Table IV., a larger proportion of country families using fresh milk and butter, a higher proportion of town families using margarine and lard.

Father's occupation.—(8) Land labourer, (9) farmer, (13) land labourer, (15) boots in hotel, (16) unemployed, (19) [woodcutter], (20) farm hand, (21) casual worker, (22) on farm, (23) [—], (25) blind, (28) boatman, (29) stapler, (31) land worker (casual), (32) coachman, (36) carpenter, (37) sweep, (40) steel factory, (42) shoe factory, (45) vineyards, (46) stableman, (48) vineyards, (49) policeman.

General Considerations.

When the results of these studies are brought together the following comparison of the nutrition of the children can be made. For the reasons already given we compare weight with age, using the British Anthropometric Standard. Table VI. gives a comparison of the percentage deficiency of weight compared with the Anthropometric Standard in the different classes.

operation was performed and a third one four weeks after that. When seen it was clear that there was a slight swelling rather above the lacrymal sac, and this gave the clue to the diagnosis, and on operation proved to be a mucocele involving the anterior part of the ethmoid.

Several cases are recorded where epiphora has been the first symptom noticed; this was so in one of my cases. It may be a useful early sign, but can occur in other tumours about this region; I recall a case in which epiphora and then dacryocystitis were said to have been for months the only symptoms of a patient who eventually died of sarcoma of the superior maxilla.

A thorough intranasal examination is naturally undertaken in all these cases, but is usually of little assistance in the diagnosis. In only two of my cases was anything abnormal detected. In both cases nasal polypi were found. In one case, a male aged 85, they were entirely unsuspected and had not given rise to any trouble. In the other case the patient said that he had had them for 14 years and had had them removed on many occasions. Other observers have recorded cases in which the outer wall of the nose was bulged inwards by the mucocele and on being punctured the size of the external swelling was considerably reduced. It is somewhat remarkable that this occurrence is not more common; it did not occur in any of my cases.

ÆTIOLOGY AND PATHOGENESIS.

The onset of these cases is often so gradual and the course so slow and painless that it is very difficult to assign a definite cause in an individual case, still less to point to any ætiological factor that is common to them all.

I will not attempt to deal with the various theories that have been brought forward, as it seems to me that for the production of the condition partial or complete blocking of the natural ostium must occur and any attempted explanation must have reference to this occurrence. There are certainly two ways in which this may be brought about. Logan Turner thinks that "one may be justified in regarding a pre-existing catarrh as the cause of the chronic inflammatory changes which take place in the affected sinuses. In consequence of the catarrh the ostium becomes temporarily or permanently obstructed and there is an accumulation of the mucous contents of the cavity and gradual thinning and absorption of one or more of its bony walls." This is certainly a good explanation of some cases, even though it is not possible to establish definite evidence of the initial catarrh, and one knows that absence of any abnormal nasal discharge is a very characteristic feature of the condition when well established. The occurrence of an injury has been suggested by Killian and others as a possible explanation and sporadic cases brought forward, but in Logan Turner's series of ten cases there is no instance of it, and he is inclined to discount it. Gerber is also very sceptical.

In my series I have at least five cases in which it can, I think, be said that a severe injury was the exciting cause. The case of the small boy who got a severe black eye at football four months before the onset of the external swelling has been mentioned, and I will briefly describe some other cases.

A lieutenant in the Air Force, whilst getting into his aeroplane, was struck in the eye by a stone thrown up by an H.E. shell. He had a black eye; it ached a good deal and never got quite right. The eye began to water, and four months later he noticed a swelling at the right inner canthus. This increased but he had no diplopia and went on flying for a year; he was then sent to England for an operation, but nothing was done, and he returned to France. Six months later double vision began and he came to England and under my care. I operated on him and found a large mucocele of the frontal sinus and ethmoidal cells. He got quite well and his diplopia disappeared in three weeks.

Another officer having been hit in the left eye by a piece of shell, went into hospital, but nothing was done. He had no trouble with his eye for nearly three years, and then noticed a swelling near the left inner canthus. He was sent home a few months afterwards with a typical mucocele of the left ethmoid, upon which I operated.

The third case I will mention is a most remarkable one.

A private soldier was bending down to pick up a bucket when something hit the ground and rebounded into his eye, causing a lacerated wound near the inner canthus; after ten days in hospital he was all right and returned to duty. Several months afterwards he noticed a swelling near the left inner canthus, and later was troubled with diplopia. Some months afterwards he came to England and was under my care. He then had a mucocele which I proposed to operate upon, and on having the usual X ray photograph of the sinuses taken we were very surprised to find that he had a large piece of metal in his sphenoidal air sinus just below the pituitary fossa. It was then clear that the piece of metal had struck the floor of the frontal sinus, ploughed through the ethmoid, and come to rest in the sphenoidal sinus. I did the radical operation on the mucocele, but thought that it would be meddlesome surgery to interfere with the piece of metal. It is still in the same place and has caused no symptoms except occasional headaches during the last three years.

Injury can, I think, undoubtedly be accepted as a cause of the condition, so that we have therefore at least two methods of causation—one inflammatory, the other traumatic. But it may be wondered why everyone who gets a nasal catarrh or sustains a severe black eye does not develop a mucocele.

My own belief is that the condition depends largely on the ethmoid, only arising when the ethmoid is of a definite anatomical configuration—that is to say, when some of the anterior cells come much further forward than usual and are found in front of the fronto-nasal duct, even in front of the lacrymal bone, and bulge into the floor of the frontal sinus. When this condition is present and the fronto-nasal duct much narrowed by it, it would take but a small amount of plastic inflammation to block it, whilst a blow near the inner canthus would readily crush this cell into the fronto-nasal duct or obliterate its own ostium. Normally, the anterior ethmoidal cells lie well behind the ascending process of the superior maxilla and are protected by it, but an unusually anterior one would be correspondingly more vulnerable.

While this seems to me a likely explanation for the majority of cases, there will always remain some few in which another cause will be revealed at the time of operation. I refer to those cases in which an osteoma growing in an anterior ethmoidal cell or near the fronto-nasal duct may gradually cause blockage.

Luc and Laurens have each recorded a case of this, whilst only the other day, as I was operating by the external route on an ethmoid I came upon a very anterior cell almost completely filled by an osteoma, which might easily have caused trouble later on.

SYMPTOMS.

One of the chief characteristics of the condition is the entire absence of symptoms until an external swelling appears. Then symptoms may arise which lead the patient to seek advice from an ophthalmic surgeon, either on account of the alteration in vision due to displacement of the globe or on account of some affection of the lacrymal apparatus.

Headache is occasionally complained of, and may be a simple "brow ague" or a generalised ache. The bursting headache usually associated with increased intracranial pressure is seldom if ever present. Only three of my patients complained of headache; in two of them the posterior wall of the sinus was found to be absent at the time of operation; the dura being exposed, was naturally somewhat pressed on by the contents of the mucocele. It is, perhaps, surprising that the headaches were not more severe in intensity, but the frontal lobes of the brain can put up with a good deal of slow compression without the rise of any untoward symptoms.

Differential Diagnosis.—The recognition of the condition may be quite easy if we have to do with a straightforward case that presents the classical signs and pressure symptoms. Some confusion may occur if an acute inflammatory process is grafted on to the previous long-standing condition and the clinical

The conclusions of previous investigators that rickets tends to affect the later members of large families is borne out by these observations.

This and the familial incidence of the disease is strikingly shown in families 11, 12, 18, 30, and 34 of the rural series.

General Conclusions.

The general conclusions of all these studies is that a state of under-nutrition affecting the growth of the children has existed in Vienna and the adjoining country. No evidence is afforded that this has been associated with any marked increase in the incidence of rickets. Life and a certain amount of activity have been sustained upon a gross energy intake of little over 2000 calories per man per day, which must be explained in the light of Benedict's finding that undernutrition markedly decreases the basal metabolism.

The great help received from the Friends' War Victims Relief Committee, who have done so much to save the lives of these children, made it possible to carry out the investigation. The expenses of the work were partly defrayed by the Medical Research Council.

PROGNOSIS IN PATIENTS PRESENTING RAPID ACTION OF THE HEART.*

By JOHN HAY, M.D., F.R.C.P. LOND.,
HON. PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.

THE difficulty and fascination of prognosis give it a foremost place in the elements of the science of medicine. Many factors are required before a satisfactory attempt can be made to forecast the future of a patient; but patients and their relatives are entitled to a clear expression of opinion. There is no more searching test of a man's knowledge of medicine than his power of accurate prognosis; such a prognosis is only possible in the presence of an accurate diagnosis, familiarity with the usual course of the disease, a correct valuation of the various symptoms, and a sure knowledge of treatment. There is no better exercise in humility than the habit of writing out the prognosis in full, and checking it by results. My subject is confined to that of prognosis in patients manifesting rapid heart action, the question of prognosis in heart disease generally being far too comprehensive to be dealt with satisfactorily in a short paper.

There is no more common deviation from the normal rhythm of the heart than increased frequency. We meet with it constantly, for the rate of the heart is at the mercy of any passing emotion, transient pyrexia, or physical effort. In most instances the cause of rapid action can be accurately recognised and rapidly assessed; but this is not always so, and it is of considerable importance that the significance of this physical sign should be recognised and its bearing on prognosis determined.

The foundation of a correct prognosis is correct diagnosis, but much more is required; a clear understanding of the nature of the rapid action may coexist with a hazy and uncertain conception of the course of the illness. The character of the heart's response to the tachycardia must be appreciated; does the heart manifest signs of distress, or does it accept the increase in rate with equanimity? The health and adequacy of the other organs must also be taken into consideration, and before any definite opinion can be ventured on it is essential that the response to treatment should be observed. All the above factors must be correlated in order to arrive at an accurate prognosis.

Two Groups of Cases: Causes of Rapid Action.

The first essential in considering any case of rapid heart action is to determine whether the rapid action is due to an acceleration in the normal stimulus

the inception of an abnormal rhythm, as fibrillation of the auricle. It is obvi accurate prognosis is possible if this qu settled. In by far the greater number senting increased rapidity of heart action is due to influences acting on the heart nervous mechanism by depressing th stimulating the accelerator nerves, or b tion of both, and the consequent distur normal balance. In the smaller group, ences are no longer effective. The sino-a is not responsible for the orderly contr heart, the "pace-maker" is side-track other point in the heart dominates the r

Under normal conditions the rate o constantly changing, and as a rule the rate are part of a compensatory mech are complementary; the change in rat of many alterations in the circulation towards an increased efficiency. The quicker in order to meet some stress Variations in blood pressure are ass variations in rate.

Function of the Heart.

The heart's only function is to supp the actual tissues. There must be supply of oxygen for "the capillary bed, space in which the real business of life is as Osler described it. For this function t there must be an adequate output of o blood from the heart every minute. increase in effort is associated with higher of oxygen by the muscles; this necess supply of blood, and the heart beats in order to increase its output. The va latter is remarkable; at rest the gener minute is 3 to 5 litres; with moderate litres; during heavy work it may reach minute—four times the amount discha rest—an increase showing the reserve normal heart and the call that may be m circulation. The two factors determini increase of output per beat and accele heart rate. The increased rapidity of chiefly responsible for increased outpu highly trained athlete there is a de output with each systole. Such is the a normal heart in an average state of hea a heart an increased rate, when a grea required, is all to the good. It is ev accurate compensating mechanism. Wh the rate is maintained at a high level w crease in output, or in the absence of an increased output, the efficiency of the he and a high rate is then detrimental.

Physiological Causes of Rapid

The causes of rapid action of the heart rhythm is physiological are emotion, effor or defective myocardium, anæmia, pyre exophthalmic goitre, neurasthenia, D.A. In all these instances a graphic record wo the auricles and ventricles contracted relation to each other. In each, the caus action is a factor outside the heart, wo the nervous mechanism, which causes th to become more active. This holds tr the heart is itself diseased, for then th rate is an attempt to provide an adeq tion with an inadequate heart; the output per beat is neutralised by t number of beats per minute. An incr cases of organic disease is an evidenc inadequacy, and is of importance in pro physical sign is of considerable value in c regurgitation, where a persistent deg tachycardia, such as 90 to 100 per min rest, is ominous. The same holds goo

NUTRITION IN VIENNA.

II.

BY MADGE R. GRIBBON, M.A.,
AND
D. NOEL PATON, M.D., F.R.S.,
Assisted by MARGARET FERGUSON, M.A., AND
ANNABEL M. T. TULLY, M.A.
(From the Institute of Physiology, University of Glasgow.)

IN the present paper* we deal with the condition of (1) the middle classes in Vienna; and (2) the rural classes in the neighbourhood of that city.

Condition of the Middle Classes in Towns.

Middle-class families have suffered more severely than those of the working classes from the adverse economic conditions because the increase in their incomes, proportionately to the increased cost of living, has been smaller and because pride has prevented them from seeking or accepting charitable help. They have been reduced to a state of penury which contrasts cruelly with their previous condition of comparative affluence. It was difficult to secure consent to a study of their conditions of life and to gain coöperation, but when this had been achieved they gave most intelligent help and rendered accuracy of result much more easy to attain than in the case of the labouring classes. They kept their ration ready to be weighed on the visit of the investigator and were scrupulously careful to note any small additions to the food such as a gift to one of the children of an extra piece of chocolate. The investigator weighed the younger children on her own balance and measured them, while she obtained the weights and heights of the others at their schools. The families were not selected but were taken as their names were given. Living in good homes—because unable to get other accommodation—the children are often forced to be absent from school for want of clothing and in some cases they are sleeping three to four in a bed as the other beds had to be sold to meet expenses. Under the present régime no room is allowed to remain unoccupied and every family, if not using all the rooms, is bound to take in lodgers. The majority of the rooms are small, on an average from 10 to 14 feet square, and such a room may be occupied by three or four people. Though the main buildings may be well ventilated, the rooms seldom are. The Viennese rarely open windows and the children are kept much indoors. Rents have not risen to any great extent, but few people are able to move from one house to another. The incomes often do not cover the weekly expenses and too frequently at each visit another article of furniture was seen to have disappeared. Blankets are made into clothes and one garment is made to do for the whole family.

Table I. gives a summary of the results of these studies.

In the families marked with an asterisk in the tables one or more of the children received a meal at school from the American Mission. The equivalent for this is stated in nems and in allowing for it the composition is taken as the same as the Friends' ration, containing 27 g. protein and 45 g. fat to 1000 calories. Two of the families with rickets—41 and 44—give results so divergent from the others that probably they should have been excluded from the series. In 41 it is noted that the mother—a widow—gets much help from her parents and could give little information. Forty-four was a country family who used some of their own products. But, since these cancel one another, it was considered better to leave them. Among the non-rachitic families several require further consideration. In 5 it is noted that the food was chiefly bread and the children were undernourished. In 20 there is no special note except that they had been selling furniture and that it was impossible to ascertain all the household expenses. For 27 it is noted that the family had a very precarious living, one week much better than the other. In 29 more than the whole income goes for food and the same is the case with 46.

In March, 1921, an attempt was made to study the diets of 10 middle-class families, including the families of three university professors at Graz and Salzburg. Although the average income exceeded that of the Viennese families, being 1435 as against 1140 kronen, the food consumed yielded on an average only 1200 calories with a minimum of 770 and a maximum of 2023 calories. It is difficult to accept such figures and the suspicion is aroused that we failed to secure a complete record of the food actually consumed. We therefore do not publish a table of the results.

TABLE I.—*Investigation of Middle-Class Families in Vienna. (Calculated as per man per day.)*

Nutrition of the Children.

While probably the weight to age ratio fails to give a thoroughly satisfactory representation of the nutrition of the children, the weight to height ratio seems also unsatisfactory in conditions where stunting of height as well as decreased gain of weight may have

---

* Section I. consisted of an account of a study of the diets and state of nutrition of the working classes in Vienna during the past year and appeared in THE LANCET, 1921, i., 474.

Auricular Flutter and Fibrillation.—When the tachycardia is caused either by auricular flutter or by fibrillation the ventricular rate is increased because of the inception of an abnormal rhythm in the auricles as already described. Flutter and fibrillation are closely related, and flutter is often the precursor of fibrillation. In both the onset is sudden, but it does not follow that the patient is aware of this change in the action of the heart. Any persistently steady heart rate of 120 or over in an elderly person should suggest the presence of flutter, especially so if there be significant variations in rate, such, for example, as a rate of 106 changing to 160, or dropping to 80. The relationship of these numbers is very suggestive. The auricles are probably contracting 320 times per minute, and each ventricular rate is a fraction of that number. At first the ventricles respond to every third auricular beat—106—107—then to every second—160—then, with a pulse at 80, to every fourth; such figures justify a definite diagnosis of flutter.

Another point of importance is the presence or absence of irregularity. With the exception of extra systoles or a sinus arrhythmia, the irregularity associated with tachycardia is almost always evidence of auricular fibrillation, and it is well to remember that extra-systoles and a sinus arrhythmia are most unusual in a rapidly acting heart. An irregular action may, however, be met with occasionally in auricular flutter.

We are on safe ground then in diagnosing a pathological rhythm when both tachycardia and irregularity are present. I propose to cite a few typical cases of pathological tachycardia and discuss the prognosis in each.

CASE 1.—A man of 70 noticed some irregularity of the heart, and that he was more easily out of breath than formerly, but otherwise there was nothing to complain of. He did not know when these symptoms first began, but thought they had developed within the last 12 months. On examination he was found to be organically sound. There was slight enlargement of the heart, no evidence of valvular disease, blood pressure not unduly raised, action disorderly and heart rate varying from 90 to 100. Exercise increased both the irregularity and the rate. He was suffering from fibrillation, and its inception had not unduly disturbed him; the myocardium carried the extra disability comfortably, the rate was not excessive, and the circulation was relatively efficient. The prognosis was clearly favourable, the reserve power was diminished but still adequate. With some restriction in the amount of physical effort he should (and did) live for years.

CASE 2.—This case is that of a young woman of 30 propped up in bed in acute distress, rapidly becoming worse; she was cyanosed, the jugular veins were distended, her breathing was rapid, and she was expectorating blood; abdominal wall tender and resistant, liver enlarged, œdema of the legs, scanty urine, præcordium tender, heart dilated, diffuse forcible slapping impulse, rate 180 to 190 per minute; action disorderly, many beats failing to reach the radial artery. First sound short, loud and sharp, accompanied by a short systolic murmur of varying intensity. The history was that she suffered from rheumatic fever when 14, at which time her heart became affected. In spite of frank mitral stenosis she had led a moderately active life with comfort. Six days previously she noticed her heart beating more rapidly, and she became short of breath. Her condition had become worse, there was troublesome vomiting and she was obviously losing ground. The acute cardiac failure from which she was suffering was due to fibrillation of the auricle attacking a damaged heart. The heart was failing rapidly, and the immediate failure was due to two factors: (1) the tachycardia; and (2) the irregularity, which interfered with adequate diastolic filling. The patient would die, and that soon, if the tachycardia persisted, her state being clearly desperate.

The immediate prognosis depended on whether her heart would respond speedily to treatment, and seeing that it was a fibrillating rheumatic heart one was justified in feeling hopeful. She had to be brought under the influence of some member of the digitalis group, but on account of vomiting the digitalis administered at the beginning of the attack had been stopped. The vomiting was obviously not due to the toxic action of the digitalis, but more probably to an engorged and irritable stomach. There were two options—either to risk the vomiting and give big doses, ♏xx. of tinct. digitalis by the mouth four-hourly, well diluted, accompanied by a hypodermic injection of morphia; or to inject a milligramme of strophanthin into a vein. In this patient the former method succeeded, and within 24 hours she was obviously improving and out of immediate danger.

Before the onset of fibrillation her heart was moderately efficient in spite of the mitral stenosis, and in such a case it is reasonable to take the view that so long as the rate is controlled by digitalis the patient will get along comfortably. Her reserve power will necessarily be less than before the onset of fibrillation; she will have to live at a lower level of physical endeavour. If she neglects to take the small daily dose of digitalis required, her heart will again race and her life will be endangered.

CASE 3.—In contrast to Case 2 consider another, a successful business man of 60, energetic and capable, who had always lived an extremely active life, and believed himself to be in perfect health. He woke in the early morning in some discomfort and distress which rapidly became urgent; sat up in bed, gasping, his face pale, almost livid, anxious expression, forehead dripping with cold sweat, complaining of pain over the heart. The cardiac thrust was outside the nipple, the action of the heart tumultuous and very rapid, the radial pulse less rapid, some of the beats full and bounding, others small and almost imperceptible; the vessel wall was unduly palpable. The interpretation was not difficult. Fibrillation of the auricle had attacked a man suffering from high blood pressure. When the heart was beating at a moderate pace the large left ventricle, though with diminished reserve, was quite capable of maintaining an efficient circulation, but the sudden increase of the rate, the irregular filling during diastole and the necessity of maintaining a relatively high blood pressure had proved too much for the left ventricle.

Here, again, the immediate prognosis depended on one thing and one thing only—could the heart be slowed? The probabilities were against it; this type does not respond so readily as the rheumatic. Strychnine, caffeine, camphor, are all useless, and atropine positively detrimental. It is of no use attempting to stimulate the myocardium—the one imperative need is to slow the heart. Given a slow action the ventricle may manage comfortably. Digitalis or strophanthin must be exhibited and the shock and distress of the patient mitigated with morphia.

The immediate prognosis was very bad; but if the heart did respond and slow down there was a possibility that the attack of fibrillation might prove transitory after persisting a few days, but there would always be a liability to recurrence. If fibrillation persisted and the heart responded to treatment, there might be difficulty in this patient in maintaining the blood pressure at a sufficiently high level, the necessary optimum required for this man, with the result that he would be permanently crippled, and at not too distant a date his heart would fail, in spite of the British Pharmacopœia.

I should mention here that in patients suffering from fibrillation there are certain features revealed by the electrocardiograph, which when present indicate damage to the myocardium and add gravity to the prognosis. I refer to ectopic beats and variations in the Q.R.S. portion of the ventricular complex; but the essential guide is the response of the heart to its new burden as indicated by the symptoms of distress.

I have lightly sketched the pictures of these three cases attacked by fibrillation of the auricle, showing how each responded. It is manifest that the response depended on the capacity of the heart to tolerate the additional load of a rapid and irregular heart.

A Different Type of Pathological Rhythm.

It is well in formulating prognosis to remember that fibrillation may occur in short paroxysms, transient in duration. It tends, however, to become permanent. Let me relate an example of a different type of pathological rhythm:—

CASE 4.—A male, aged 31, who came under observation because of variations in his pulse-rate; he experienced little, if any, discomfort, but his medical attendant was anxious about him because, without apparent reason, the heart contracted at 140 per minute for a time, and would then drop to about 90 or possibly become irregular. The history was that four months before, when at sea, he had "gone sick," and a diagnosis of pericarditis had been made. On reaching Liverpool he was admitted to a hospital where he remained three months, being treated for "pericarditis." During this time his heart rate varied, and on being cross-examined he gave the prevailing rates as 70, 90 to 95, and sometimes a very rapid action. Treatment had entailed rest and some digitalis. When discharged the action of the heart was still unsatisfactory, although it caused him no distress. The prognosis was of special importance because

It will be seen that in all three the nutrition is least affected during the first two years, that it is most markedly affected during the years of active growth following weaning, that during the period of decreased rate of growth from 4 to 10 it again falls, but that in the town families it shows a tendency to become more marked during the second period of active growth, above 10 years of age. This is least marked in the country families and most marked in the middle-class families. The country families suffer less than the urban and this may be correlated either with their more open-air life or with their somewhat better diet as shown in Table VII.

Up to about eight years there is no marked difference in the deficiency of height in the three groups, but after this age the rural children fall more markedly below the standard of height, while showing a less deficiency in weight. The cause of this is not apparent. In all three groups the height of the mother was rather above the Anthropometric Standard, but in the rural families the fathers were more distinctly below it than in the other groups. In the working-class families they were actually above it. Possibly growth may have been reduced by too early work in the fields.

Rickets.

Our study included 424 children, urban middle-class, urban working-class and rural, and 108 of these, or 25 per cent., showed signs of rickets, past or present. MacGregor † found that of 1277 children between the ages of 6 months and 10 years admitted to a Glasgow fever hospital, 44·4 per cent. of those born in Glasgow of Glasgow parentage, 33·8 per cent. of those born in Glasgow but having country-bred parents, and 25·1 per cent. of country-born children of country parentage showed evidence of rickets. Further, Kassowitz, before 1910, stated that 89 per cent. of children admitted to hospital and 59 per cent. of his private patients in Vienna manifested signs of rickets.

The evidence thus does not indicate that there has been the marked increase in the disease since the war which is commonly stated to have occurred. It would rather seem that attention being directed to the condition has led to its diagnosis in children in whom it would not have attracted attention in former times. In Glasgow and in other cities where rickets is prevalent—and Kassowitz's figures indicate that it was so in Vienna—parents are apt to regard it as inevitable and of little moment and they rarely consult a doctor about it unless in severe cases. Further, the fact that in so many families a considerable proportion of the children above the age of 6 show rachitic deformities indicates that the condition had developed before war conditions were established. The cases of rickets were distributed among the different groups as shown in Table VIII.

TABLE VIII.—*Distribution of Rickets.*

—	Total No. of children.	Rachitic children.	
		Number.	Per cent.
Working class (urban) ..	153	43	28
Middle class (urban) ..	124	21	17
Working class (rural) ..	117	44	30

In the working-class families it occurred in 58 per cent. of the families. In the middle-class families it occurred in 35 per cent.: the type was generally mild and it usually affected the younger children. In the rural families 26 out of 50 families had cases of rickets —52 per cent.—and the deformities were frequently very marked.

The high incidence of rickets in the rural families with their higher intake of natural milk fats is of interest. A comparison of the diets of the three groups (Table VII.) does not indicate that the lesser incidence of rickets in the middle classes is associated with a greater consumption of milk or other fats.

case being 10–15 mg. A lower potency than this has been observed by us in a well-known brand of Norwegian medicinal cod-liver oil sold in this country. It is to be noted that these liver oils originate from fishes belonging to the genus Gadus, and we are now investigating whether oils of other genera also exhibit this exceptionally high vitamin-A potency. The relative potency of Lofoten and Finmarken medicinal oils and the influence of the mode of preparation of the liver oils on the vitamin content will form the subject of a separate communication.

The expenses of this research were defrayed from a grant made by the Medical Research Council, to whom our thanks are due.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF

GANGRENE FOLLOWING MEASLES.

By Eustace Thorp, O.B.E., L.R.C.S. Edin., D.P.H.,
DEPUTY MEDICAL OFFICER OF HEALTH, SUNDERLAND.

The following case appears worthy of record owing to the rarity of gangrene as a complication of measles and to the extreme youth of the patient. I have up to the present found no other case recorded.

M. M., aged 4½ years, was admitted to the borough infectious diseases hospital under my care on the fourth day of disease suffering from measles. She had had bronchitis at nine months and pneumonia when aged 2. On examination she presented a typical measles rash and signs and symptoms of broncho-pneumonia. She was obviously very ill, temperature 104°F., breathing difficult, and some cyanosis. Temperature remained high, in the region of 104° and 105°, and on the ninth day some meningeal symptoms intervened. These subsided on the eleventh day, and on this day a few dark purple spots were observed on the left leg and both limbs showed signs of circulatory troubles and became cold and pale. Active treatment was begun. a few septic spots were observed on the cheek and one on the abdomen. Within the next 24 hours gangrene made its appearance on the toes of the left leg and rapidly spread up that leg to the region of the knee-joint, a well-marked line of demarcation forming at the level of the junction of the *upper and middle thirds of the tibia*; at the latter part of this period of 24 hours a patch of dry gangrene was observed on the great toe of the right leg. The condition of the child was such that it was not thought advisable to operate and she died on the fifteenth day of the disease. A post-mortem was refused. Blood specimens were submitted to the bacteriologist and negative results obtained for the Widal test and for pathogenic organisms.

A CASE OF MULTIPLE SARCOMATA.

By John A. C. Macewen, M.B., C.M.,
F.R.F.P.S. Glasg.,
SURGEON, GLASGOW DISTRICT HOSPITALS.

The following case presents some features of interest.

J. G., a woman of 46, was admitted to Duke-street Hospital in February complaining of tumours in both breasts and one on the back. She had had 11 children, the youngest being about a year old, but the right breast had never lactated. The tumour on the back had been present for about eight years, had steadily increased in size, and had always been painful. That in the right breast had been present for about six weeks prior to admission, while that in the left she had only noticed recently.

On examination the tumour in the lumbar region was seen to resemble a spina bifida in shape and general appearance, and was covered with glazed, dark-coloured skin. It was not movable, and while firm to the touch suggested fluctuation on deep palpation which, however, caused considerable pain. The tumour in the right breast presented as a hard irregular mass in the upper and outer quadrant, and was slightly tender to palpation. The breast as a whole was unduly firm, but moved freely on the underlying structures. There was no puckering of the skin, retraction of the nipple, or enlargement of axillary glands. The left breast presented a small hard and tender swelling on the inner side. The tumour in the lumbar region was first operated on and removed without particular difficulty. It contained about 2 oz. of blood-stained fluid surrounded by quantities of necrotic tissue, and it grew apparently from the spines of one or two lumbar vertebræ, portions of which were removed along with the tumour.

Dr. R. M. Buchanan reported the fluid negative to tests for cerebro-spinal fluid. The tumour presented a highly vascular capsule encircling tumour tissue in great part necrosed. Another portion of tissue examined presented a dense fibro-vascular capsule of very varying thickness with small spicules of bone in places, and, centrally, tissue of the character of spindle-celled sarcoma. The right breast was also removed and Dr. Buchanan reported the tumour as a spindle-celled sarcoma.

Patient declined further operation and left the hospital, but in the interval the mass in the left breast had increased in size, the nipple was retracted, and the glands in the axilla were enlarged. We were informed that she became blind some time after leaving hospital.

Were the tumours in the breasts primary or were they secondary to the tumour in the lumbar region, and, if so, what was the channel of metastasis? Unfortunately, the pathological characters of the tumour in the left breast, clinically resembling a carcinoma, could not be ascertained.

A CASE OF

INTRAPERITONEAL RUPTURE OF THE BLADDER

DUE TO RETROVERSION OF THE GRAVID UTERUS.

By Dorothy Chattaway, M.B., Ch.B. Birm.,
SENIOR HOUSE SURGEON, MATERNITY HOSPITAL, BIRMINGHAM.
With a Note by Lewis Graham, M.S. Lond.,
F.R.C.S. Eng.

The following case is of sufficient interest to merit record.

Mrs. P., aged 25, was admitted to the Maternity Hospital, Birmingham, on June 10th, 1921, with acute abdominal symptoms complicating a four months pregnancy. Her general health had been good; she had had two previous labours, the first a breech presentation, the second normal. The history was that a fortnight before admission the patient had retention of urine for 48 hours followed by incontinence. No catheter was passed. On the afternoon of June 9th—i.e., 30 hours before admission—she became rapidly worse. She was seized with sudden acute abdominal pain and passed no urine after this.

On admission she was obviously very ill, pale, and collapsed, pulse 120 and feeble, temperature 99·2° F., respiration 40. She complained of severe abdominal pain. The abdomen was distended and tender all over. The uterus could be felt the size of a four months pregnancy. There was free fluid in the abdominal cavity. A catheter was passed and 20 oz. of urine withdrawn. This contained thick pus, blood, and shreds of bladder epithelium. The patient had a slight "show" shortly after admission. On vaginal examination the os was dilated and the foot presenting.

The case was seen by Mr. Lewis Graham and a diagnosis of intraperitoneal rupture of the bladder made. The abdomen was opened at once. The peritoneal cavity contained over a gallon of turbid foul urine. The bladder was contracted and a rupture about 2 inches long was present at the fundus. This was sutured with catgut. The abdomen was drained by one large drainage-tube. The patient's condition after operation was very grave and an intravenous saline was given. The fœtus was expelled at 8 A.M. the following morning, the placenta, which was adherent, being removed manually.

The patient made a good recovery. She wore a self-retaining catheter for a fortnight and was catheterised at regular intervals till June 25th when she first passed urine normally. She left hospital on July 11th quite well.

Note by Mr. Lewis Graham.—The interesting features of this case are its great rarity and the fact that a patient was able to make an uninterrupted recovery after having a large amount of foul urine in the peritoneal cavity for 30 hours. The diagnosis was obvious and the treatment easy, although when first seen the patient appeared moribund and not worth operating on. However, an operation was her only chance, and she made the above remarkable recovery.

In patients belonging to this group the diagnosis is generally obvious, and the prognosis is dependent on the general condition rather than the tachycardia. I do not propose to deal with them in detail, but will touch on one or two points of importance.

Tachycardia in Children: Toxic Tachycardias.

Not infrequently children are brought for an opinion because of rapid heart action. On examination the heart is found normal in size and there is no evidence of valvular disease, but the rate is 100 to 120 per minute and often more after games. With this the child is otherwise healthy, joins in the games vigorously, without discomfort or distress. It is well to remember that excitement and exercise may affect the heart rate in children to a remarkable degree, and if the child is healthy in every other respect, if the tachycardia is not accompanied by distress or discomfort and does not interfere with eating or sleeping, then I should not veto ordinary school life and games, provided there is reasonable supervision.

The tachycardias due to toxæmia are important, and the prognosis in any particular patient depends on whether the source of the toxin can be localised and dealt with. The gums, the accessory sinuses, the tonsils, and the gastro-intestinal tract must be surveyed. These patients present, perhaps, the greatest difficulty.

A most important form of toxic tachycardia is that met with in early tuberculosis, in which a rapid action of the heart may be the dominant physical sign, associated with some degree of pallor and lassitude. Physical examination of the chest may give little help—frequently there is a moderate degree of pyrexia, and this in itself may partially account for the tachycardia; but tachycardia is sometimes present in the absence of pyrexia—the apyretic tachycardia of early tuberculosis. Such a combination of tachycardia and normal temperature in early tuberculosis is significant and justifies a very grave prognosis. Such patients rarely respond well to treatment; their progress is steadily downward.

Value of Response to Effort.

In the attempt to arrive at a prognosis in nervous patients and those suffering from neurasthenia and D.A.H., *the response to effort is helpful.* For example, if the rate of the heart is 110 when seated, reaches 130 or 140 after a short period of moderate exercise, and then drops within three minutes to 80 or 90, the probability is that the myocardium is sound and exercise beneficial, if carefully supervised. The response to effort should also be estimated by careful cross-examination concerning the degree of the distress induced by the actions of ordinary life; the mentality of the patient being taken into account, and when possible the accuracy of the statements checked by personal observation.

It might be well to emphasise here the fact that in many instances tachycardia occurring in patients with valvular disease is not caused by or due to the valvular trouble, but is a pure neurosis. This is noticeable in patients suffering from mitral stenosis.

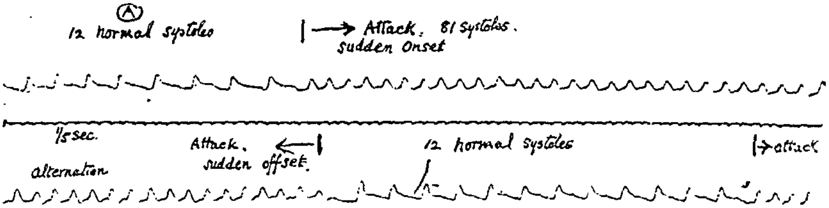
In the group which we have been considering it is of the greatest importance to discover the cause outside the heart responsible for the tachycardia, which is secondary to emotion, effort, anæmia, sepsis, or some other cause.

Primary Tachycardia.

In the second group the tachycardia is primary; the cause of the rapid action is in the heart itself, and in such patients the first step is to recognise the nature of this essential change. There are three forms: (1) Paroxysmal tachycardia; (2) auricular flutter; and (3) auricular fibrillation.

Paroxysmal Tachycardia.—One characteristic of an attack of this type is the suddenness of its onset, of which patients are often able to give a clear and decided account. When the tachycardia occurs in short spells the offset is also definitely dramatic. The attack terminates abruptly, and quite unlike the gradual slowing down of a burst of palpitation in a nervous patient. Rest, emotion, or effort do not modify the frequency during an attack of paroxysmal tachycardia.

The tracing here shown is from a patient during recurrent attacks of paroxysmal tachycardia. The paroxysm was preceded by 12 normal beats, consisted of 81 abnormal beats, and was followed by another series of 12 normal systoles before the recurrence of the pathological rhythm. In this patient the rapid action of the heart sometimes persisted for hours or even days. This condition of paroxysmal tachycardia is not common, and a diagnosis from simple palpitation with rapid action, in the absence of any opportunity of investigating an attack, *may have to be made solely on the description elicited* by careful cross-examination of the patient.



Radial records showing the onset and offset of a short attack of paroxysmal tachycardia. Alternation is present in some portions of the record.

In most instances the outlook is not grave. The patients are usually young, and the healthy heart of the young tolerates short paroxysms of rapid action without much discomfort; fortunately the paroxysms are rarely prolonged. The outlook is less satisfactory when the rate is extreme, when the duration of the bursts of heart hurry extends *into days or weeks*, and when the heart shows *signs of distress*. This is especially likely *to be the case* if there is old-standing *heart disease*, when a persistent rate of 150 to 200 beats *per minute* soon exhausts the myocardium, and *the patient runs* the risk of dying of cardiac failure. Even a healthy heart shows signs of distress as the result of a prolonged paroxysm, but it is possible to promise a rapid and remarkable return to a normal condition with the cessation of the paroxysm.

The most important *factor* influencing prognosis is the *extent to* which the presence of the rapid *rate distresses* the patient; this will depend on the rate of the heart during an attack, on *the age* of the patient, the presence of cardiac disease, and the frequency and duration of the paroxysms. In a small percentage of the cases the ectopic stimulus arises in the ventricle and not in the auricle or node, and it is agreed that in such patients the outlook is bad. This fact can only be recognised by means of the electrocardiograph.

its use in medicine. The paragraphs on the use of digitalis are open to criticism, for the action of the drug and indications for its use are not stated in clear terms, as is possible in the light of the newer exact knowledge that we have of its action. The author appears to think that it raises blood pressure, an opinion that requires definite qualification; moreover, the discussion of its applicability in mitral and aortic disease before the statement of its use in auricular fibrillation tends to give a wrong impression.

More than a hundred pages are devoted to the endocrine glands and organo-therapy, and the author's remarks on this subject are a useful counterpoise to the optimism of the advertisements and brochures that describe commercial preparations of endocrine glands; at the same time the account of the clinical application of certain preparations, the specific activity of which is still in doubt—for instance, of corpus luteum extract—seems unduly confident. There are excellent chapters on practical therapeutic measures, specific therapy, and the general principles of dietetics. Separate parts are devoted to the consideration of general physical measures, such as electricity, hydrotherapy, massage and climate, of drug and industrial poisoning, the treatment of emergencies and some simple skin lesions. The last chapters deal adequately with medical ethics and contain useful advice to young physicians.

It will be seen that the book covers an immense field. The author is obviously inspired with high ideals and his writing is something more than an expression of opinion and a record of fact. His style is epigrammatic and direct, and one of the themes which run through the work is the effort to remove the mystery that tends to cling to drug treatment by demonstrating its real value on simple lines.

First Aid and Rescue Work in Mining.

By LOUIS G. IRVINE, M.D., B.Sc. Edin. With Prefatory Note by J. S. HALDANE, M.D., F.R.S. Johannesburg: South African Red Cross Society. 1921. Pp. 348.

IN a little book which presents an entirely new combination of facts and knowledge on first aid and mine rescue work, Dr. L. G. Irvine contends that "it is far better in practice to train a limited number of persons well, than to give a smattering of knowledge to a larger number." The value of public first-aid competitions and demonstrations in maintaining efficiency is undoubted, and Dr. Irvine's book will stimulate interest in these matters in South Africa, where interest is much needed. The subject of mine rescue work is advancing so fast in this country that text-books dealing with its practice are soon behind the times. For example, the few pages devoted to training and organisation of mine rescue work seem to be behind that suggested by our Coal Mines Act. The regulations of this Act provide an excellent scheme of organisation which has been put into practice, especially in the northern colliery district.

Part I. deals with anatomy and physiology on similar lines to our advanced manuals on the subject. Special emphasis is laid on first aid in mining accidents, with useful practical points often omitted in such handbooks. The physiology of respiration is not as detailed as it might have been, while the illustrations are more than usually clear and explanatory. In Part II. the equipment and organisation of first aid in mines is brief, little more than two pages of South African law being included in this section. The Red Cross plank stretcher is ceratinly worthy of adoption by mine managers in this country, owing to the impracticability of our ordinary stretchers in the awkward places met with during transport in a mine. The chapter on gaseous impurities in mines and their effects gives a good résumé of known facts, though the matter might be more clear and concise. The author gives precedence to nitrous fumes over sulphuretted hydrogen as a mine air impurity, a point which has long been neglected by previous authors on this subject. The description of sulphuretted hydrogen gas as reminiscent of "rotten eggs" is omitted in this volume; Dr. Irvine suggests "gob stink," a somewhat undefinable odour, as an indication of the presence of this gas, and repeats the same warning as a means of detecting carbon monoxide.

The account of the ways of detecting gases for mine rescue purposes is poor. Dr. Irvine maintains that a canary is not to be depended on to detect CO/0·1 per cent. (p. 332), although he admits the use of canaries as the only practical means of detection of this poisonous gas, without adducing experimental evidence to support it. He also states that if air is seriously deficient in oxygen, small animals will show symptoms of embarrassment before effects are produced on man. It has been shown, however, that a mouse will live in 7 per cent. or even less of oxygen, where a man would probably collapse, and in this country at least the condition of a mouse or canary cannot be used to give warning of deficiency of oxygen.

This book on the whole contains a handy collection of data which should be a valuable addition to first aid and mine rescue literature.

Intestinal Toxæmia;

or, Auto-Intoxication in the Causation of Disease. By ALEXANDER BRYCE, M.D., C.M., D.P.H.Camb. London: Andrew Melrose, Ltd. 1921. Pp. 180. 6*s.*

THIS book deals with a subject of great interest to the medical profession, for whom it is chiefly written; at the same time the author expresses a hope in the preface that his book may appeal to a wider public. Intestinal toxæmia is defined as "the auto-intoxication which owes its origin neither to food contaminated before it is swallowed, nor putrefying because of its content of noxious germs, but which arises from the digestion of foods by the bacteria normally present in the digestive tube." Had the subject been limited by this definition it might have been dealt with in the 180 pages which make the book, but unfortunately the author has been carried by his enthusiasm over an immense field of medicine which is largely unknown ground. Thus, on p. 27 the following among others are given as the causes of intestinal toxæmia: all dyspepsias, stasis from whatever cause, muco-membranous or other colitis, chronic nasal catarrh, adenoids and enlarged tonsils; all infectious disorders such as influenza and measles, and all conditions which reduce the toxicolytic power of the bowel, such as deficiency of digestive juices, alcoholism, tubercle and rheumatism. Only a method as orderly and condensed as that adopted by Liddell and Scott in the compilation of their dictionary, or as general in treatment as that adopted by H. G. Wells in writing a History of the World, could succeed in giving a clear view of the subject in so small a compass. Dr. Bryce's weakness is in his method, which consists alternately in explicit quotation from scientific work with exact reference to page and volume, and bald statement of a highly speculative kind. For instance, on p. 68, "it is an absolute certainty that pernicious anæmia can be produced by such small amounts of toxins as can be absorbed into the system from pyorrhœa alveolaris." There is also a tendency to express theories as facts, as in the statement that Still's disease "is due to an infection of the alimentary canal by the staphylococcus citreus." The book is written with the ardour of a missionary, and many diverse and interesting facts discovered in the course of recent research are correlated in a manner that stimulates the reader to new lines of thought and reflection. Putting aside the questions of sub-infection and bacteriæmia there are few who will disagree with the author's main thesis that intestinal toxæmia is responsible for much ill-health.

he wished to get married. Medical justification for marriage depended in the first instance on the diagnosis.

Whether he had ever had pericarditis I do not know; there was certainly no evidence of it when I saw him, but his statements as to the peculiar and significant variations in his pulse-rate during his illness were most suggestive and indicated the presence of auricular flutter. A pulse-rate of 70–94–140 is most easily explained by an auricular rate of 280 with a 4 : 1 or a 3 : 1 or a 2 : 1 ratio, and this was proved to be the case by polygraph and electrocardiograph. A condition of auricular flutter having been demonstrated it was satisfactory to find that the patient was little, if at all, disturbed by the varying rhythm, and though the heart was larger than normal there was no evidence of valvular disease or cardiac distress. Up to this point the outlook was good if the flutter could be arrested. Had the flutter persisted in spite of treatment, the prognosis would have varied according to the degree of slowing produced and maintained by digitalis.

Prognosis now depended on the response to treatment. To test the possibility of cutting short the flutter, the patient was again put to bed, and on May 7th 1 drachm of the tinct. digitalis was given daily. After 7 drachms had been taken the flutter ceased and was replaced by fibrillation. The dose of digitalis was then increased to ʒ ii. daily, and within 24 hours the action of the heart was normal. The question had become narrowed down to the probability of further attacks of a similar nature; no certain answer could be given, because there is a definite tendency to recurrence when once flutter has manifested itself, but it was reassuring to know that even if they recurred, adequate treatment would probably cut them short. Under the circumstances one did not feel justified in standing between the patient and his marriage.

Flutter, then, may present itself as an isolated attack which is never repeated. There may be numerous short paroxysms extending over many years, or the flutter may continue for months or years, and eventually pass into a normal rhythm. Much less satisfactory is the change into fibrillation when and if the latter persists, for this rhythm proves a still greater strain on the staying power of the heart. Experience has shown that when flutter occurs in paroxysms the first is generally the least severe. The most reliable guide to prognosis is the degree to which the heart and circulation are distressed by the rapid action, and the prognosis is always unfavourable in the presence of old-standing myocardial or chronic valvular disease.

Summary and Conclusion.

The rapid action met with in Group 1 is a symptom and nothing more; the manner of systole is normal, the rhythm is physiological. The element of danger is not in the rapid action but in the reason for its presence. The prognosis will depend on an accurate understanding of the primary cause and the possibility or otherwise of remedying it. In Group 2 the rapid action is fundamentally different. It originates in the heart itself. It is a disease rather than a symptom. The actual contraction of the heart is abnormal and less efficient. In some patients the auricles and ventricles contract simultaneously, and in the majority the auricles have ceased to take any share in the circulation. The presence of tachycardia and irregularity is evidence of the existence of a pathological rhythm.

The immediate danger to the patient results from the exhausting effect of the rapid and relatively inefficient action of the heart. The faster the rate the greater the danger. The prognosis improves as treatment is effectual in slowing the heart. Rate for rate the prognosis is graver if the action is irregular. Irregularity results in inadequate filling of the heart during diastole.

In every case the immediate prognosis depends on the manner in which the heart has responded to the extra strain entailed by the sudden change in the rhythm. The accuracy of the more remote prognosis will depend on an acquaintance with the usual course, followed by the various forms of rapid action under differing conditions.

Of the three divisions of Group 2 the following is the order of severity: (1) paroxysmal tachycardia; (2) auricular flutter; (3) auricular fibrillation; and of the rheumatic and arterio-sclerotic types of fibrillation the rheumatic is on the whole more amenable to treatment.

VITAMIN-A CONTENT OF OILS

PREPARED FROM LIVERS OF THE COD, COAL-FISH, AND HADDOCK.

BY S. S. ZILVA, D.Sc.,

AND

J. C. DRUMMOND, D.Sc.

IN a previous communication in THE LANCET[1] attention was drawn to the exceptionally high content of vitamin A in cod-liver oil. The necessity of studying the preparation of this oil was urged in order to ascertain whether the best conditions were observed in its preparation. This problem has since been taken up by us as a part of an extensive investigation on the vitamin-A value of edible oils. During the early part of this summer we had the opportunity of visiting the Norwegian fishing grounds, where we inspected a number of cod-liver oil factories and where we collected numerous samples of oils of different origin and from different stages of the various processes of preparation. These samples are now in progress of being investigated in our laboratories.

The origin of the livers from which the medicinal cod-liver oils are prepared is of special interest. The Norwegian cod-liver oils are made from livers of fish caught near the Lofoten Islands and off the Finmarken coast. The fishing off the Lofoten Islands takes place between the end of January and the end of April. The catch during this season consists almost exclusively of mature cod which come to spawn on the coastal banks of the islands. After the spawning season is over these cod migrate to the Finmarken and eventually to the Murmansk coast. They reach the former place the end of May, where they join shoals of immature cod coming from the north. The physiological condition of the cod fished off the Finmarken coast is therefore different from that of the cod fished off the Lofoten Islands, since the Finmarken cod consists mostly of spent mature and immature fish. Another striking characteristic of the Finmarken oils is that they are mixed, owing to the fact that besides the cod (*Gadus morrhua*) other gadoids—namely, coal-fish (*Gadus virens*) and haddock (*Gadus aglefinus*) are being caught at this time in the Finmarken waters. In most of the Finmarken cod-liver oil factories the livers of the fishes mentioned above are worked up together, and consequently the so-called "cod-liver oil" from Finmarken is seldom pure cod-liver oil and may even sometimes contain no cod-liver oil at all. It was therefore our first problem to ascertain the relative potency of cod, coal-fish, and haddock liver oils.

The oils were tested out quantitatively by the method devised by Zilva and Miura and described elsewhere. By this method it was previously found that a daily addendum of 2 mg. of certain crude cod-liver oils was sufficient to promote growth in rats which had ceased growing owing to a deficiency of vitamin A. The high potency of such oils can be realised when one remembers that as much as 0.5 g. of butter is sometimes required to achieve the same result. The above oils were, however, of unknown origin. The oils utilised in this experiment, on the other hand, were collected by us personally in Finmarken, and prepared from the unmixed livers of the respective fishes caught this season in that locality. They were clear, slightly yellow oils, composed of the first two fractions drawn off the steamed livers. The pure cod oil was found just as potent as the liver oils hitherto tested out quantitatively, a daily dose of 2 mg. being required to induce the resumption of growth in rats. Coal-fish oil was even a little more active; slightly less than 2 mg. was found to be the minimum daily dose. Haddock oil, although not so active as the cod and coal-fish oils, showed also a high potency, the minimum daily dose in this increased sexual desire" (p. 69), but does not point out that it is purely speculative, though expressed in anatomical terms that seem much more convincing than psychological ones. The chapter on Ethical Considerations is a plea for reality-thinking instead of the false modesty and prudery that lead youth to learn in a prurient school a faulty antithesis between morals and reality. The final chapter, on Treatment, contains a demand for knowledge on the part of the instructor, and its tone can be indicated by the sentence, quoted from Brill: "It must not be imagined that robbing masturbation of its horrors encourages the practice."

---

[1] Zilva, S. S., and Miura, M.: THE LANCET, 1921, i., p. 323.

The book is not a mere product of enthusiasm, as so many on "sex enlightenment" tend to be, but a scientific study of a subject the complexities of which are fully realised by the author.

A MANUAL OF VETERINARY PHYSIOLOGY.

By Major-General Sir F. SMITH, K.C.M.G. Fifth edition. London: Baillière, Tindall, and Cox. 1921. Pp. 892. Price 31*s*. 6*d*.

IN this well-tried manual Sir Frederick Smith's aim has been to show the bearing of physiology on the practice of veterinary medicine, surgery, and hygiene, a task of no little difficulty in view of the still very imperfect knowledge of the pathology of disease in animals. As Director-General of the Army Veterinary Service his opportunities of observing the working of the digestive and locomotor systems in horses were unrivalled. It is natural, therefore, for the book to be more confident in its treatment of equine than of bovine physiology. The arrangement of the subject is a section on each bodily system in turn, beginning with the blood and the heart, and ending with generation and development, two more general chapters dealing with Growth, Decay, and Death, and the Chemical Basis of the Body completing the book. The author has not only produced a noteworthy book but has known how to keep pace with the advancement of his subject. Undoubtedly, he is right in regarding laboratory team-work as essential for further progress.

VITAMINES—ESSENTIAL FOOD FACTORS.

By BENJAMIN HARROW, Ph.D., Associate in Physiological Chemistry, College of Physicians and Surgeons, Columbia University. London: George Routledge and Sons, Ltd. 1921. Pp. 219. 10*s*. 6*d*.

DR. HARROW has made a good effort to present in a popular form the subject of nutrition, with special reference to accessory food factors. The title of the book is rather misleading, as only the second half deals with vitamins, the first part being devoted at considerable, if not unnecessary, length to calorie values, carbohydrates, fats, and proteins. The chapter on amino-acids and quality of proteins is the most succinct. The space so occupied might well have been given to the subject of vitamins, since this important part of the work consequently suffers from curtailment. Many more illustrations of the effects of the deficiencies due to absence of vitamins in the foods could have been included so as to emphasise the importance of these factors in the diet. In fact, the description of the vitamins is not quite on the level of recent teaching, and several minor errors occur. Extreme sensitiveness to touch is not characteristic of rickets, this symptom being due to complication with infantile scurvy. Bloch's cases of keratomalacia, which were cured by cod-liver oil and a whole-milk diet, are quoted as evidence of an association between vitamin A and rickets. If rickets is mainly associated with the absence of vitamin A (assuming sufficient B and C vitamins to be present in the ordinary food) it should now be possible to cure and prevent the disease. In any case the general reader will do well to keep himself informed of the work being done on this and kindred questions, and a popular book such as Dr. Harrow's should help to disseminate useful knowledge.

MATERIA MEDICA,

With Notes on Prescription Writing. By JAMES BURNET, M.A., M.D., Ch.B., M.R.C.P. London: J. and A. Churchill. 1921. Pp. 80. 4*s*. 6*d*.

THIS small book is one of the "Students' Synopsis Series," and is intended to aid the medical student in his study of materia medica. The various chemicals and drugs are arranged alphabetically, a very brief description being given of each; the doses are noted and the official preparations are enumerated. We think the author has made too great sacrifices for brevity. The information supplied is often incomplete; botanical source and natural order of the vegetable drugs are only rarely stated, and the descriptions are sometimes inadequate for recognition purposes. The last ten pages of the book contain a few useful notes on Prescription Writing, Incompatibility and Solubility.

JOURNALS.

BRAIN. Vol. XLIV., Part 2.—Percy Sargent: Lesions of the Brachial Plexus associated with Rudimentary Ribs. This is an analysis of 65 cases and the author's conclusions are as follows: (1) Variations in the composition of the brachial plexus are apt to be associated with costal abnormalities, prefixation with a seventh cervical rib, and postfixation with an abnormal first thoracic rib. There is, however, no regular relationship between the costal and neural anomalies. (2) Of the several different types of cervical rib met with clinically that which most frequently requires treatment by operation is represented by an abnormally large non-jointed costal process, continued onwards as a dense fibrous band, to be attached to the first thoracic rib behind the sulcus nervi brachialis. (3) Symptoms of gradual onset result from continual slight traumatism to the eighth cervical root or lowest cord of the plexus, caused by the tightening of the band during respiration and in certain movements of the arm. (4) With a post-fixed plexus symptoms referable to the first thoracic root may be caused by the pressure of a normal first thoracic rib. (5) Vascular symptoms are vaso-motor in origin and result from injury to the sympathetic fibres shortly after their entrance into the eighth cervical and first thoracic roots. (6) The results of operative treatment in 50 cases have been traced for a period of from 2 to 12 years. Pain was cured in 19 cases and relieved in 8. Muscular wasting was cured in 12 cases, relieved in 12, and unrelieved in 7. Vaso-motor symptoms were cured in 14 cases, relieved in 6, and unrelieved in 2. Operation is not called for in all cases. Gentleness of manipulation, clean dissection, and a bloodless operative field are essential.

C. U. Ariens Kappers: On Structural Laws in the Nervous System; the Principles of Neurobiotaxis. After some historical remarks the author begins with the observation of Cajal that "if during embryonic development new axons pass to some region of the central nervous system, ganglion cells may approach these axons in two different ways, either by sending forth long dentrites or by a migration of the cell body itself." Kappers has found that this shifting of nerve cells is a very common occurrence, and he maintains as a result of his comparative researches on the topographic differences of homologous cell-groups in the central nervous system of vertebrates that it is determined by the places from which the largest number of excitations reach the cells; further, that not all excitations but only those with a functional relationship to the cell-group in question will cause this shifting. Next, whereas the growth of the dentrites is a stimulo-petal tropism, the growth of the axon bears a stimulo-fugal character. The occurrence in the same cell of two opposed tropisms the author believes to be due to a bio-electric influence, a species of galvano-tropism. The investigations of Sven Ingvar recently have proved the electric-galvanotropic character of the outgrowth of the axon.

A CASE OF
COMBINED EXTRA- AND INTRA-DURAL HÆMORRHAGE; RECOVERY.

BY M. L. TRESTON, M.R.C.S., L.R.C.P. LOND.,
CAPTAIN, I.M.S.; SURGICAL SPECIALIST, INDIAN ARMY.

THE case here described is that of a young, well-developed Hindu. He was found unconscious, in the early hours of the morning, some distance from his camp, and was sent to the nearest base hospital, at Basra. On investigation it appeared that he had had an argument with one of his companions the night before which ended in a set-to fight with sticks.

On admission.—The patient was comatose and breathing stertorously. Temperature 102° F., pulse low and bounding. There was marked bruising, but no external wound, over the left side of the scalp, with congestion of both eyes, slight proptosis of the left eye, and dilatation of the left pupil. The right upper extremity was paralysed. A diagnosis of extra-dural hæmorrhage was made, and an immediate operation undertaken. There was no fracture of bone to be discerned beneath an extensive and œdematous skin flap. A ¾ inch trephine was applied over the Sylvian point, and on removal of bone blood gushed out, dark and with clots at first, but rapidly becoming arterial. It was found to be coming in jets from the bony canal of the middle meningeal artery, at the antero-inferior angle of the parietal bone. The bone was carefully chipped away, and the proximal end of the artery found and ligatured.

This part of the operation completed, the dura projecting into the wound was seen to be bluish-black in colour, tense, and pulseless. A crucial incision was made into it, and a mass of blood clot gently removed. The clot, about 1½ inches in extent, was lying over the divisions of the Sylvian fissure, and extended into the main limb of the fissure for a short distance. No bleeding points were observed after removal of the clot, and the brain surface appeared healthy. The opening in the dura was closed and the skin flaps sutured.

Progress.—The patient regained consciousness 12 hours after the operation. The wound healed by first intention, and the movements in the upper limb began to return slowly. But there was complete motor aphasia; the patient could not write, and his efforts at speaking only resulted in a long drawn ŏ. He understood what was said to him and could read and make his wants understood by signs. During the four weeks he was under observation improvement in arm movements continued, but the aphasia remained the same.

The case is of interest in view of recovery from extra-dural hæmorrhage, combined with intra-dural hæmorrhage, and with damage to the motor speech area.

TWO UNUSUAL GYNÆCOLOGICAL CASES.

BY J. C. HOLDICH LEICESTER, M.D., B.S., B.Sc., M.R.C.P. LOND., F.R.C.S. ENG.,
LIEUT.-COLONEL, I.M.S.; PROFESSOR OF MIDWIFERY AND GYNÆCOLOGY, MEDICAL COLLEGE, CALCUTTA; SURGEON TO THE EDEN HOSPITAL FOR WOMEN, CALCUTTA.

THE following cases are sufficiently unusual to be worth recording. The first, an example of malignant disease infecting the cervix after a subtotal hysterectomy for what was apparently a simple fibroid growth, also shows what an extensive growth can be present with such a short and trifling history.

CASE 1. *Columnar carcinoma occurring in the cervix left after a subtotal hysterectomy.*—Mrs. W., aged 40, came to see me on August 3rd, 1920, with the following history. She had been twice married, had had three children, the last 16 years ago, and one miscarriage at the fifth month, 14 years ago. In 1913 she had had the uterus removed by subtotal hysterectomy, apparently for "fibroids," and had not menstruated since. Two months ago she had a very slight blood discharge from the vagina; this occurred again one month ago, lasting only half an hour or so in each case; otherwise she was feeling perfectly well. On abdominal examination nothing abnormal was detected except a movable right kidney. On pelvic examination the cervix was found to be freely movable, but rather hard, with slight ulceration on the left side, bleeding on examination. On August 5th, under chloroform, I removed a small wedge-shaped piece of the cervix for examination which Major F. P. Mackie, Professor of Pathology at the Calcutta Medical College, kindly cut for me and reported as definitely showing malignant changes. On the 20th, under chloroform, I removed the whole cervix and upper part of the vagina by the extended method of Wertheim. None of the glands were involved. The patient made an uninterrupted recovery and was discharged on Sept. 25th; the vagina had healed and there was no thickening to be felt anywhere. The patient then underwent a course of radium treatment and has remained well up to now. Major Mackie kindly examined the specimens for me and reported an extensive growth of columnar carcinoma in the cervix, but so far as could be seen the operation had removed a good margin of healthy tissue all round.

CASE 2. *Early rupture of a tubal gestation.*—P. M., a Bengali, aged 27, was admitted to the Eden Hospital on Feb. 5th, 1920, with the following history. She had had seven children, the last seven months ago. She had had two menstrual periods since her confinement, the last being from Jan. 12th to 17th, which was normal in every respect, and came at the proper date. At 7 A.M. on Feb. 5th, on getting out of bed, she suddenly felt very ill with pain in the lower abdomen on the right side, which had gradually increased up to the time of her admission to hospital at 2 P.M. Condition on admission: patient blanched, pulse 142, soft and small; abdomen was somewhat distended and tender but not hard; some dullness in both flanks. Per vaginam some sense of fullness noted on the right of the uterus. A diagnosis of ruptured ectopic pregnancy was made. The patient was prepared for an operation, which was performed about two hours later. On opening the abdomen I found a fair amount of dark blood-clot, and on examining the pelvic organs there was a slight dilatation of the right Fallopian tube in the isthmic portion, about the size of a marble, which had ruptured. The tube was removed and the abdomen closed, 1¼ pints of normal saline being left in the peritoneal cavity. Nearly one pint of blood and blood-clot had been removed from the abdomen. The patient had some fever for the first four days, but after this she made an uninterrupted recovery.

Reviews and Notices of Books.

THE PRINCIPLES OF THERAPEUTICS.

By OLIVER T. OSBORNE, M.A., M.D., Professor of Therapeutics, Yale University. Philadelphia and London: W. B. Saunders Company. 1921. Pp. 881. 35s.

THERE is an opinion prevalent in certain advanced circles that the drug treatment of disease is relatively useless and that the prescription of a bottle of medicine will soon be a thing of the past. It is a refreshing change, therefore, to read the dicta of Prof. Osborne that "the absolutely drugless treatment of acute and really tangible chronic illness is a myth"; that "drugs must be, and are used legitimately for the vast majority of all patients"; and that "if there is nothing the matter with a patient, of course he can be cured of what he did not have by what he does not get." The book is divided into 15 parts, of which the first deals with general principles, and in it the need for the introduction of the metric system is emphasised. Parts 2 and 3 concern the preparations, prescription, and therapeutics of the valuable drugs of the U.S.A. Pharmacopœia. Only useful drugs that have a demonstrable activity are described, and the author advises simple prescriptions containing the best official preparation of the drug and, if soluble, in the most agreeable solution. The therapeutic action of drugs is discussed on sound lines from the clinical and empirical standpoint, and the subject is simplified by the exclusion of drugs of doubtful value and the omission of many preparations. Readers may vary in their opinion as to whether the author has made a wise selection in his choice of drugs, and some will find their favourite drugs omitted; thus there is no mention of sodium bicarbonate and sodium chloride in the treatment of cough, nor is there any reference to tolu among expectorants. Prof. Osborne states that there is no excuse for the use of squills as an expectorant, and that heroin has no activity not shared by codeine; he even says that the tendency of heroin to cause a pernicious habit should preclude

FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of
Professor CHARLES ACHARD, PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PARIS. AND Dr. CHARLES FLANDIN, D.S.O., CHEF DE CLINIQUE À LA FACULTÉ DE PARIS.

ARTERIAL HYPERTENSION:

ITS CLINICAL MEASUREMENT, PATHOGENESIS, PROGNOSTIC VALUE, AND TREATMENT.

BY DR. L. A. AMBLARD,
FORMERLY INTERNE, PARIS HOSPITALS; MÉDECIN CONSULTANT, VITTEL.

THE earliest research work upon arterial tension and its application to current clinical practice, was carried out at the same time by Potain in France and Bach at Vienna. During the period from 1897 to 1907 practically all the work on the necessary instrumentation, on pressure, and on the methods of use of the knowledge gained, was performed outside France, by Mosso, Sahli, Riva-Rocci, Recklinghausen. Hill and Barnard, Oliver, Janeway, Erlanger, and others. In France, however, Marfan, Teissier, and Bouloumié must be mentioned; also Huchard, who demonstrated in a continuous series of publications the extreme importance of arterial hypertension, making of it the capital symptom of arteriosclerosis. In other countries the various pressures, systolic, diastolic, and mean, together with pulse pressure, were studied; in France up to 1907, before the publications of Amblard (of Vittel), the systolic pressure alone had been the object of measurement and study.

At this time Amblard showed the importance of simultaneous measurements of maximum and minimum pressures, and described the method, based on the work of Marey, and called the "oscillation method," which is now most commonly employed. Shortly afterwards he produced his sphygmometroscope for measurement of the two pressures; by this oscillation method the maximum pressure is obtained automatically and with precision.

Eventually Pachon produced his manometric sphygmometer, a perfected form of Pal's sphygmoscope, the coloured liquid indicator of which is replaced by a needle moved by the modifications of a capsule which retains a constant tension no matter what degree of pressure is applied to it. Since that time new work on arterial tension and its measurement, symptomatology, diagnosis, and prognosis, has constantly been published. Amongst all this research may be especially noted that of Vaquez. Widal, Josué, Amblard, and Gallavardin, in whose recent considerable work on "Arterial Tension in Clinical Practice" are set forth and discussed the most recent advances in this subject. The perfecting of apparatus has facilitated very complete clinical study of tension; the knowledge now at hand of maximum and minimum pressures links this clinical study up with physiological study, and considerably enlarges a hitherto narrow field of clinical research, permitting the hope that in a short while the estimation of the functional power of the heart will become a matter of ease; its difficulty is lessened almost daily by the publishing of fresh information.

Causation of Arterial Tension.

Arterial tension is the result of two antagonistic elements which equilibrate each other: (1) the force of contraction of the left ventricle, which tends to drive the blood from the centre to the periphery, and (2) the resistance offered to the flow by the more or less accentuated closing up of the small peripheral blood-vessels. This resistance to the flow is only susceptible to minimal variations from one moment to another. The force of ventricular propulsion is intermittent in its increase of the blood content of the arterial system. The pressure to which the arterial wall is subjected varies constantly, growing under the influence of the blood increase to a maximum—the maximum arterial tension, rapidly attained and then rapidly diminishing during the period separating one wave of increase from the next. Maximum arterial tension, then, is the index of ventricular effort; minimum tension is the index of resistance to the blood flow. In a young man the space separating these two pressures—the variable or pulse pressure—is about 60 mm. Hg, and the figures of normal tension range from 120 to 140 mm. Hg maximum, and from 70 to 85 mm. Hg minimum. When either factor—either cardiac contraction or peripheral flow—is modified, modification also results in the figures noted above. If modifications take place in the same direction, the conclusion may be drawn that the degree of tension has varied in the same direction; if the modifications are in opposite directions, no immediate conclusion can be arrived at concerning the modification of the degree of tension. That is to say, it is absolutely necessary, in order to estimate the arterial pressure of a subject, always to note the maximum and minimum pressures.

Measurement of Arterial Tension.

The importance accorded at the present time to arterial tension necessitates precise measurement. Some writers have attempted manometric improvements, others have worked to limit as far as possible the subjective element of measurement, and to substitute the automatism of a tactile instrument. At present two fundamental methods of measurement are employed in France, being undertaken by different means. The first of these methods is that of appreciation of tension by observation of altered blood pressure in a segment of a limb under the influence of a compressor placed on that limb. Of this type is Potain's sphygmomanometer, in which a rubber bulb is used to compress the radial artery, this bulb being connected with a metal manometer which indicates the degree of external pressure on the artery; the indicator, placed on the radial artery below the point of compression, shows the modification of blood pressure caused by that compression; the point of disappearance of pressure indicates the maximum. This instrument, the first to be designed for the purpose, is difficult to handle in spite of its apparent simplicity, and its recording of results is so influenced by personal equation that its employment is rapidly becoming more restricted. Based on the same principle of compression are the method of Riva-Rocci and those derived from it, in which is used a rubber brassard, the moment of disappearance of the pulse at the radial artery being registered. Satisfactory results are thus obtained, mainly because digital palpation is replaced by an oscillating indicator which, as in the methods of Vaquez and Barré, permits very exact measurement of the maximum tension. The Riva-Rocci apparatus also permits study of minimum tension by means of two procedures based on modification of pressure below a compressed point. One of these, called Ehret's method, consists of progressive decompression of a previously distended brassard; the growing amplitude of pulsation is felt by a finger inserted beneath the edge of the brassard. At a certain moment a particular vibration of the pulse is felt; this point past, the pressure rapidly diminishes. The figure read on the manometer at the moment when the amplitude of the brachial pulse begins to diminish is that of minimum pressure. The other method, called that of Korotkow, consists of the same application and inflation of the Riva-Rocci brassard, and of estimation of the sounds made by the passage of the

PHARMACY.

Materia Medica and Pharmacy for Medical Students. Fourth edition. By REGINALD R. BENNETT, B.Sc. Lond., F.I.C., Pharmaceutical Chemist. London: H. K. Lewis and Co., Ltd. 1921. Pp. xxiii.+264. 7*s.* 6*d.*

THAT a fourth edition of this handy summary of materia medica and pharmacy has been called for is in itself evidence of the value of the book, and shows that it fills a useful place in the student's library. The present edition resembles its predecessors, but has been enlarged by the inclusion of further information regarding the action and uses of the drugs and the conditions and diseases in which their preparations are given. The first 24 pages are introductory, and define various pharmaceutical terms used in the pharmacopœia and others in common use but unofficial. Then follow brief remarks upon the nature of the various plant principles, and a summary of the system of weights and measures used in medicine. In the main part of the book all the drugs in common use are described, with their botanical source, constituents, and official preparations; they are grouped according to their pharmacological action. The last sections give valuable dose tables, and four appendices deal with various types of incompatibility and with the phraseology of Latin directions in prescriptions. A good index completes the volume. The information given is both concise and reliable, and we recommend the book to medical students.

Drugs in Commerce: Their Source, Preparation for the Market, and Description. By JOHN HUMPHREY, Ph.C., F.J.I. London: Sir Isaac Pitman and Sons. 1921. Pp. ix.+116. 3*s.*

THIS volume is the latest addition to the Common Commodities and Industries series. Mr. Humphrey begins with a short introductory chapter describing the routes by which drugs are brought to this country and the kind of packages in which they arrive. There follows a series of six chapters giving a brief account of the commoner drugs (including those official in the British Pharmacopœia) arranged in alphabetical order. Each is briefly described in such a way that the reader may be able to identify it; the botanical and geographical sources are given and the active principles enumerated. A brief account of the method of collection and preparation for the market is included; but the natural orders of the plants and animals yielding the drugs are not given. The book is intended more for the general reader than for the specialist in pharmacognosy, and will serve a useful purpose in giving concise and accurate information on roots, rhizomes, stems, leaves, flowers, fruits, seeds, gums, resins, gum-resins, &c., as well as on the products of animal origin used in medicine, either in a crude state or for the preparation of galenicals. The illustrations include several photographs of drug packages and sale rooms, and line drawings of a number of the more important drugs.

THE CARE AND FEEDING OF CHILDREN.

Ninth edition. By L. EMMETT HOLT, M.D., LL.D., Professor of Diseases of Children in the College of Physicians and Surgeons, Columbia University. London: D. Appleton and Co. 1921. Pp. 149. 4*s.*

THIS little manual, which first appeared in 1891, has now reached its ninth edition, having been revised and enlarged so as to incorporate the more modern teaching on infant care. The book is written in the form of a catechism, the directions and explanations being given throughout in such simple language as admirably to adapt it for the use of the mothers and of the nursery nurses to whom it is addressed. Some, at least, of the recommendations made by Dr. Holt would not be unreservedly endorsed in this country. The five meals daily advocated for children during their second year would be considered excessive by many authorities. The quantity of milk recommended is also far in excess of that usually given during the second year, about 40 oz. daily being advised, and for children of three to seven a quart daily. Excellent formulæ are given for the various modifications of cows' milk, but there is no mention of the citration of milk as an alternative to excessive dilution. A valuable feature in the book is the stress laid upon the principles underlying infant feeding. An introduction is contributed by Dr. Eric Pritchard, who expresses the belief that the manual will act as an incentive to the establishment in this country of training schools for nursery nurses similar to those founded in America by the author.

MEDICAL CONDUCT AND PRACTICE.

A Guide to the Ethics of Medicine. By W. G. AITCHISON ROBERTSON, M.D., D.Sc. London: A. and C. Black, Ltd. 1921. Pp. 168. 6*s.*

THIS is a very good little book, and contains information upon more subjects than the important one of how the young practitioner should behave. Ethics for medical men, and indeed for all men, are admirably summed up in that portion of the Catechism of the Church of England which is known as "My Duty towards my Neighbour." But there are special problems connected with medical work and practice which can only be answered by a medical man who has attained ripe years. Dr. Robertson's book contains the solution of such problems, together with counsel upon the period between qualification and the commencement of practice. The advice in this chapter and, indeed, throughout the whole book is full of sound common sense, and the young practitioner who follows it will be saved many a stumble in his professional walk of life. Chapter XIV. deals with the question of medical secrecy, which is at the present moment exercising the minds of medical men to a great extent, and all will not agree with some of Dr. Robertson's views as expressed in the chapter which we have mentioned. One very useful part of the book is an indication of the manner in which Scots law differs from that of England in certain points. Considering its size, the book is extraordinarily complete, and there is only one matter in which we think that Dr. Robertson has failed to be explicit, namely, in the paragraph about the administration of anæsthetics (p. 153), where he would have done better to give a warning that it is unwise for a medical man to administer an anæsthetic to a female patient except in the presence of a third person.

AUTOEROTIC PHENOMENA IN ADOLESCENCE.

Second edition. By K. MENZIES. London: H. K. Lewis. 1921. Pp. 100. 5*s.*

IN a recent number of a well-known American medical journal we read: "The climax . . . . . is not infrequently consummated in the doctor's office when the youth is bluntly confronted by the crippling results following masturbation." The underlying assumption is common in this country, and when evidence for it is sought there often arises a storm of protest such as follows only when our most irrational beliefs are questioned. The laity firmly believe in the dreadful effects of masturbation, and there results an enormous amount of mental conflict and remorse, often increased if the sufferer seeks aid or advice. The only literature likely to reach him is written by quacks, or by well-intentioned people who vie with them in attributing a terrifying host of evils to the practice.

Most medical text-books give scanty and almost furtive references to the subject, and the appearance of a second edition of Mr. Menzies's book indicates that it has satisfied a want. He accepts and uses psycho-analytical theories (perhaps a time will come when it will not be necessary for so many writers to give us preliminary expositions of these theories), but he quotes freely from authors of all views. He mentions Bang's view that "with every irritation of the urethra there is a corresponding irritation of a certain portion of the brain, which irritation excites the person to true arterial hypertension has been made possible without danger of confusion with other circulatory states having the appearance of hypertension. Measurement of maximum tension alone, when abnormally high, as in patients with aortic insufficiency, has led to these cases being considered hyperpietic; but the complementary information given by concomitant measurement of minimum tension furnishes an important distinction between pure aortic insufficiency—e.g., in typhoid and rheumatism—and insufficiency due to specific aortitis. In the former class the affected valve no longer opposes during diastole the reflux of blood from the aorta towards the ventricle (this condition is indicated by a diastolic murmur); an abnormal depression of tension in the arterial system at the moment of diastole is the result. There is, then, diastolic hypotension. But as it is necessary to ensure circulation that the blood be impelled from the heart towards the periphery under a certain mean pressure, minimum hypotension must be compensated by an exaggeration of maximum tension; thus in pure aortic insufficiency are found habitual tensions of 170–60, the maximum exceeding the normal maximum of 140 by 30 mm. Hg and the minimum not attaining the normal minimum of 80. In specific aortic insufficiency the pressure readings may appear to be those of pure insufficiency so long as a renal sclerosis has not produced its customary effect of hypertension. At that moment it is not possible to distinguish the nature of the trouble by measurement of tension alone. Only when renal sclerosis has progressed sufficiently does distinction become possible, for at that moment the elevation of minimum tension to the normal level—or above it—indicates the specific nature of the cardiopathy. With the figures 240–100 mm. Hg, for example, specific aortic insufficiency is certainly present, with an already considerable renal lesion. I do not emphasise the fact that the transient hypertension arising by painful crisis in tabes, or that due to excitation of a heart already prodigal of effort, or an excessive tachycardia, can slightly raise the pressure; I prefer to confine my attention to true persistent hypertension.

True Persistent Hypertension.

Two principal factors may modify the pressure: exaggeration of the force of ventricular contraction (maximum hypertension) and exaggeration of resistance to the flow (minimum hypertension). Except in cases where under some transient influence—e.g., emotion—contractile energy is momentarily exaggerated, the maximum tension is only exaggerated to the precise degree necessitated by that elevation of the minimum tension to which it is subordinate. This minimum hypertension can be referred to two mechanisms: (1) The venous congestion which, supervening in advanced phases of valvular affections, cannot be without effect on the flow of blood in the small peripheral arterioles; (2) much more important, the obstruction of these small arterioles. The true hyperpietic subject is one in whom a peripheral spasm raises the minimum tension and renders necessary a maximum tension sufficient to maintain the outward circulation from the centre to the periphery (Amblard). Normally minimum tension is about 70 mm. Hg, and maximum about 130 mm Hg, the various arterial pressures which arise being contained within the limits of 60 mm. Hg. A minimum hypertension of 40 mm., for example, necessitates a maximum hypertension of 100 mm. But various intervening factors (notably the elasticity of the arterial wall, which varies with the causal malady and with functional abnormality) so modify normal functions that the rise of minimum tension is always accompanied by a proportionately larger rise of maximum tension—e.g., a minimum of 120 mm. Hg demands a maximum of from 200 to 220 mm. Hg. If the necessary space between the maximum and minimum figures is maintained, circulation will be ensured under conditions abnormal but relatively satisfactory. The cardiac muscle becomes hypertrophied to perform the extra work imposed upon it by the anatomical or functional defect of the arteries until it slowly or rapidly breaks down. Clinically, hypertension sometimes appears, frequently associated with more or less marked troubles relating to renal insufficiency; but sometimes very careful investigation—qualitative and quantitative—of renal function and of the rhythm of urinary elimination gives no sign indicating disturbance of these functions; arterial hypertension is then the only symptom reported. In the first instance it is easy to connect the hypertension with a renal lesion and to act accordingly (hyperpietic nephritis of Widal); in the second instance it is more difficult to confirm this relation.

Any infection can cause lesions of chronic nephritis and the condition of hypertension. But the latter seems particularly closely allied to the evolution of syphilis (which disease should always be examined for in a hyperpietic patient), apart from several very clear cases where supervening events can be unhesitatingly connected with a recent affection (e.g., scarlatina) frequently complicated by nephritis, or with an evident intoxication (e.g., lead poisoning).

Clinical Divisions of Hyperpietic Subjects.

Clinically, hyperpietic subjects may be divided, from an ætiological standpoint, into several groups, as follows:—

1. Patients, usually young, in whom hypertension follows more or less recent scarlatina or acute infection.
2. Cases of industrial lead poisoning, common in the labouring class, exceptional in other classes.
3. Young hereditary syphilitics, the type of whom is the arterio-sclerotic of about 25 years of age, with hard arterial walls, whose radial arteries "roll" beneath the finger, who have apparently healthy kidneys and an arterial tension of about 170–100 mm. Hg, and in whom arterial hypertension is connected with a sclerosing process resulting from specific hereditary distrophy.
4. Hereditary syphilitics at a later age, when renal lesions at first insignificant have developed; and also other syphilitics, 20 years after their infection, the type of whom is the hyperpietic patient of 45, who admits infection, or denies it deliberately or in good faith.
5. Senile sclerotics, the type of whom is the hypertensive patient of 65 or 70, in whom the hypertension is of mixed origin, being partly functional, due to peripheral arterial spasm, but chiefly connected with senescence of the arterial walls.
6. Other patients in whom syphilis is not detected, who are perhaps sound in that respect, but have gout or diabetes (although in many cases of hypertension during these two diseases syphilis, hereditary or acquired, must be suspected, and only dismissed from possibility after very careful examination).
7. Lastly, patients with transient forms of nephritis of unknown infective origin, in whom the hypertension remains constant for a while, but diminishes with the causal affection.

I consider all permanent hypertension to be of renal origin, and clinical evidence seems to support the contention; the hypertension, at first isolated, has added to it by degrees various disorders, not previously present, of renal insufficiency. When there is no albuminuria, no abnormality of diuretic rhythm, no disorder of renal function, it does not follow that the kidney is anatomically intact; possibly we owe this apparent anomaly to insufficient means of appreciating renal function. In the statistics of Janeway, and in those of Fischer, dealing with post-mortem findings in numerous cases presenting permanent arterial hypertension, the cases showing indubitable renal lesions were very few.

Causation of Hypertension.

It is, however, the possible existence of these cases of isolated hypertension which has permitted Gull and Sutton to attribute to hypertension another cause—namely, hindrance to the flow of blood by generalised arterial lesions, the kidney being ultimately affected, but the morbid condition arising in the arteries. The results of Tripier and Brault seems to run counter to this theory; these writers scarcely recognise the existence of generalised arterio-sclerosis, admitting only that of lesions localised in

That the galvano-tropism of the dentrites is actually opposite to that of the axon has also been confirmed experimentally by him. In trying to explain this opposite tropism we are immediately struck by the fact that this cathodic shifting only occurs with those parts of the neuron which contain Nissl substance; the axon which contains no Nissl substance exhibits a shifting in the opposite direction. This chromidial substance has been shown to have an acid character, and Hardy's researches show that acids favour the shifting towards the cathode of the colloidal fibrillæ that are suspended in it. The neurotropic theory explains mono-axonism as a result of the polar localisation of the anodotropic part of the cell, whereas poly-dentritism is based on the fact that the cell plasm has no place of predilection and is everywhere sensitive to the cathodic tropism. Lastly, the selectivity in the formation of neuronal connexions may be explained by the raised positive surface potential which appears near the cell shortly after some previous stimulation and which immediately follows its stimulation. Therefore the axon of a cell will be attracted to that cell among many adjacent ones with which it is functionally correlated, and upon this, no doubt, depends the connexion of the nervous system with the muscles.

J. L. Birley and L. S. Dudgeon: A Clinical and Experimental Contribution to the Pathogenesis of Disseminated Sclerosis. The paper contains the results of the clinical and bacteriological examinations of 35 cases, together with animal inoculations in 15 instances and a critical résumé of the work published in recent years on this subject. The clinical records are very full and illuminating. The following are the main conclusions. It is useful to recognise two clinical types of disseminated sclerosis: a remittent type and a chronic progressive type, which occur in the present series in the proportion of six to one. In early cases of the remittent type, once the acute disturbance has subsided the patient may present no clinical evidence of organic disease over prolonged periods. The possibility of spontaneous cure cannot, therefore, be entirely denied. The two types are to be regarded as manifestations of one and the same disease. The result of cultural and microscopic examination of the cerebro-spinal fluid is negative and no specific organism has been isolated in this series of experiments. The authors regard the transmissibility of the disease from man to animal unproved. They consider that the evidence in favour of the assumption that the pathogenic agent is a spirochæte is incomplete and in many respects unsatisfactory, and that the origin and nature of the morbid agent must for the present remain sub judice. But the evidence is overwhelmingly in favour of the view that the morbid process underlying the disease is inflammatory in character.

W. E. Gye: The Experimental Study of Disseminated Sclerosis. This is a record of the injection of cerebro-spinal fluid from cases of disseminated sclerosis into 129 rabbits and 15 guinea-pigs. Seventeen of the rabbits became ill and paralysed; the guinea-pigs all remained in good health. The author discards the suggestion that the animals which became paralysed suffered from that form of paralysis which is a frequent occurrence in rabbits kept in captivity, and he concludes, therefore, that disseminated sclerosis is probably an infectious disease and that the virus may sometimes be found in cerebro-spinal fluid.

M. G. Marinesco: Report on a Case of Myoclonic Encephalomyelitis of Malarial Origin. The case simulated the myoclonic form of encephalitis. The majority of the voluntary muscles were subject to myoclonic movements; the tendon reflexes of the limbs were abolished; the pupils were equal and reacted to light and accommodation; the abdominal and plantar reflexes were absent. There was slight rigidity of the neck and delirium. Lumbar puncture showed ten lymphocytes by division and the blood an intense mononuclear leucocytosis with numerous hæmatozoa and crescents. Post mortem, the striking features were thrombi of leucocytes in the veins of the cerebral cortex, the optic thalamus, the lenticular nucleus, the caudate nucleus, the grey substance of the peduncle, the red nucleus, and the corpora quadrigemina. In the white substance there was new growth of neuroglia of peculiar formation resulting in nodules. The size of these nodules was from 130 to 210 μ and they have been seen only in the deep white matter. Marinesco gives them the name "malarial nodules." Hæmatozoa were found in many cerebral capillaries in large numbers, but a search for them in the spleen, liver, suprarenal capsules, and ovaries was without result.

J. T. Wilson: The Double Innervation of Striated Muscle.

ANNALS OF MEDICAL HISTORY. June, 1921. New York: Paul B. Hoeber. 1921. Pp. 201. $2.50.—The editor, Dr. Francis Packard, may be congratulated upon this number of the Annals; Cardan and Montaigne, Byrhtferd of Ramsey are names which should interest everyone, though most probably the last named is unknown to the majority of English-speaking readers. There are also striking sketches of two American medical men—namely, Charles Caldwell and Lafayette Bunnell, the discoverer of the Yosemite. Dr. J. S. Taylor's paper on "Montaigne and Medicine" will certainly lead those who know their Montaigne to read him again, and those unfortunates who do not, to widen their minds by making a beginning of study.—Dr. Charles L. Dana recalls Cardan's famous visit to Edinburgh in 1552 to consult upon the case of that singularly disreputable prelate John Hamilton, Archbishop of St. Andrews, the very type of bishop to have "ordered a tomb in St. Praxed's Church" had his life not been cut short by the hangman. Dr. Dana mentions that Cardan on his return journey from Edinburgh went to see Frisius, the mathematician of Louvain, and incidentally remarks that "Doctors were often mathematicians in those days"; but he makes a slip when he goes on to illustrate this point by referring to Sancho Panza's remark when he fell off his mule, "Send for an algebraist." The word "algebra" in mediæval and even later times meant primarily redintegration and so bone-setting, while the Spanish word for a bone-setter is still "algebrista." That was what Sancho asked for, and not for a mathematician. The term occurs again in the incident of the fight with the Knight of the Mirrors (p. 35, vol. iii., of Duffield's translation): "The two went on . . . . until they reached a village where they had the good luck to find an algebraist who prescribed . . . ."—One of the most interesting papers in the number before us is that by Charles and Dorothea Singer entitled "An Unrecognised Anglo-Saxon Medical Text," being an account of the Handbook of Byrhtferd, an eleventh century MS. in the Bodleian. The MS. did contain a diagram, of which only a fragment remains, but fortunately this diagram had been copied into a MS. existing in St. John's College, Oxford, which is reproduced. The diagram illustrates the correlation of the macrocosm and the microcosm and the doctrine of the physical and physiological fours—e.g., four seasons and four ages of man; four humours and four cardinal winds, and so on. The diagram also contains two circles showing the relations of the months to the movements of the moon.—Dr. William Middleton gives a graphic account of Dr. Charles Caldwell. He was active in sanitary reform, but his character made him difficult to get on with.—A particularly interesting paper is that by Dr. Casey Wood on the First Scientific Work on Spectacles, published in Seville in 1623 and written by Benito Daca de Valdez, Notary of the Holy Office.—Among the reviews is one by Dr. David Riesman upon the Regimen Sanitatis. Therein he makes a statement which cannot be allowed to pass without protest; he talks of "the short stirring couplets of Celano's 'Dies Iræ.'" That wonderful composition happens to be written in trochaic triplets.

the pressure is not compatible even with very defective function of the vascular system, and the patient dies of progressive asphyxiation.

In other cases the heart fails slowly, with a terminal phase of progressive weakening of maximum pressure, whilst the minimum pressure remains at a sufficiently high level on account of the spasmodic toxic element which previously necessitated its elevation, and of the disorder induced in the peripheral flow by venous congestion associated with dilatation of the cavities on the right side of the heart. This failure is marked by an important auscultatory sign—i.e., presystolic gallop—and by modifications of the pressure curves during routine exercises, which were used, notably during the war, to record the coefficient of myocardial resistance to effort in soldiers undergoing examination. When the heart is beginning to tire, and can scarcely continue to perform the work entailed by persistent hypertension, the maximum and minimum pressures rise, but the elevation of maximum is not what it should be, because of ventricular deficiency; the necessary effort is made through a rapid and considerable increase of pulse-rate. Signs of circulatory trouble (œdema of the limbs, hepatic and pulmonary visceral stases, ascites) habitual in valvular patients correspond, in the last phase of arteriosclerosis, to these disorders of pressure.

Importance of Recording Pressures.

The possibility of recording hypertension when the condition apparently exists alone and only displays a slight degree of renal insufficiency makes of the pressure reading a clinical sign of capital importance, since it permits treatment of nephritis from its onset, before it has been manifested by any trouble otherwise appreciable. At this stage modifications of diet and certain drugs have more chance of slowing down the process of sclerosis; arterial hypertension is in this case an important danger-signal—its mere appearance proving an apparently completely healthy subject to have already received serious damage. As regards prognosis, hypertension seems to assume a degree of gravity in accordance with the age of the subject. In the aged, where the sclerotic and atheromatous process is long established and where renal insufficiency often exists, hypertension does not seem so important as in younger subjects. By the latter are meant patients of 45, in whom the symptom is always serious, and sometimes very serious. Although the gravity of very high figures cannot be denied in a general sense, the degree of maximum hypertension does not exactly indicate the patient's danger. The relation between maximum and minimum is more important in this respect, and the pulse pressure, which shows the functional value of the left ventricle. As the minimum pressure is raised, the maximum pressure is also raised—for reasons which cannot be detailed in this short study—but to a greater extent.

Treatment of Hypertension.

In spite of the knowledge recently acquired concerning the pathogenesis of hypertension, the secretion of hyperpietic renal substances, and the excess in the blood of adrenalin, cholesterin, or uric acid, therapeutic progress has not been remarkable. Whatever may be the starting point, the essential cause, of excess of pressure, it appears that a slow progressive thickening of the kidney necessitates a continuous and progressive exaggeration of arterial tension in order to ensure satisfactory urinary depuration. The excess of minimum pressure, due to peripheral spasm, only exists to the degree in which it is useful, and the excess of maximum pressure only to the degree rendered indispensable by the elevation of minimum pressure. It would be illogical to attempt directly to lower the maximum pressure, for such a lowering would only express the insufficiency of myocardial effort to perform an indispensable supplementary task. What must be aimed at is the lowering of maximum pressure by removal of its cause—i.e., the elevation of the minimum pressure. The latter is due to toxic disorder; as Huchard has constantly pointed out, the treatment of arterial hypertension resolves itself into treatment of organic intoxication by decreasing the supply of toxin with an appropriate dietary régime, and by facilitating the removal of endogenous toxins by stimulation of normal functions of intestinal, renal, and cutaneous elimination.

With the exception of certain cases in which sudden pressure arises during habitual hypertension and necessitates urgent methods (bleeding, cupping by scarification, use of amyl nitrite, sodium nitrite, erythrol tetranitrate, &c.), the treatment of hypertension is lengthy. Together with antitoxic measures, treatment of the arterial walls is attempted; potassium iodide has been used with success, although the mechanism of its action remains unexplained. At the same time direct attempts to reduce pressure may be cautiously initiated; the Royat baths are indicated as inducing a lowering of pressure. Bubbly and thermo-electric baths, particularly the latter, have also a violent effect upon circulation; their administration should be carefully supervised, and since the effect produced is rapid but transitory, they can only be considered as an adjuvant form of treatment. Electric treatment with high-frequency currents is also an adjuvant, having no clearly perceptible effect on hypertension, but being of use in the restoration of sleep and diminution of nervous troubles associated with hypertension in irritable patients.

It must be borne in mind that the condition begins, has its continuation, and ends through intoxication (Huchard); a diet as little toxic as possible is therefore indicated. Milk, cream, butter, fresh cheese, well-ripened fruit, and vegetable soups form the basis of treatment. It cannot be too often emphasised that only by continuous adherence to the alimentary régime can a marked and lasting lowering of pressure be obtained. Only small quantities of salt must be permitted, less on account of the disputable hyperpietic action of sodium than on account of knowledge of the nephritic origin of hypertension and the fear of more or less latent chloruria.

Although the absorption of meat seems in some hyperpietic patients to have no effect on the pressure figures, it is nevertheless certain that in the majority of cases the dropping of meat diet is accompanied by a diminution in those figures, together with disappearance of toxic troubles accompanying pressure, notably dyspnœa and headache. Although a continued milk, or milk and vegetable, diet may often be unacceptable to the patient, and although in some cases it may even be impossible to overcome individual intolerance to it, there is at present no other means of maintaining a lowered pressure. Intestinal stasis is combated with frequent purgatives, and diuresis is ensured by the use of theobromine; the former difficulty of the insolubility of this very active medicament has been overcome by utilisation of a new composition sufficiently soluble even for subcutaneous injection. To various diuretic preparations may be added tisanes of couch-grass, cherry stalks, and maize. A few doses are sufficient.

In conjunction with these methods of securing diuresis it is necessary to prescribe a diuretic mineral-water cure at Vittel or Evian; the waters at Vittel are more active, being cholagogue and laxative as well as strongly diuretic. Diuretic cures cannot be satisfactorily carried out except in these spas. There is no doubt that the ingestion of large quantities of water augments œdema or raises the arterial pressure. It can be affirmed, in accordance with the views of specialists in these treatments, that, far from augmenting the quantity of water retained in the system, the diuretic cures—however paradoxical the statement may seem—are essentially dehydrant cures; the dechloridising action of the Vittel waters also contributes to the explanation.

In conclusion, the foregoing has shown that if the diuretic cures almost always provoke hypotension on rational lines, this is only one of their many advantages; the disappearance of other signs of intoxication, when the latter are present, affords a proof of the fact.

blood through the brachial artery during decompression. These sounds are noted by means of a simple binaural stethoscope, or of a similar stethoscope in which the end-piece is replaced by a small metal cup at the edge of which is stretched a tense membrane (Laubry's sphygmomanometer). After sufficient education of the ear it becomes possible to recognise the arterial sounds to which the figures of maximum tension correspond, and the cessation of clear arterial sound, to which correspond the figures of minimum tension.

The Oscillometric Method.

Another method, based on Marey's experiments, is that in which measurement is obtained by the study of modifications in blood pressure induced by various known counter-pressures applied by means of a brassard placed as in the methods previously mentioned. This last is a principle absolutely different from that on which the apparatus described above is founded. In England Hill and Barnard had already utilised the oscillations of a manometric needle to measure minimum tension; I myself first described the technique of measurement of maximum and minimum tensions by this method, which I named the "oscillation method." Its advantage lies in the certainty of the physiological data obtainable, and in the knowledge of maximum and minimum tensions and pulse pressure, and (by means of suitable apparatus) of the action of the circulation during application of various known pressures. My "sphygmometroscope," which I invented for the clinical application of this oscillation method, consists of a brassard 17 cm. broad fitted tightly to the arm and connected with a sensitive manometer of a large size, arranged to record by oscillations of a needle the exact size of impulse, irrespective of the degree of counter-pressure on the elastic capsule. Compression is obtained by means of a rubber bulb, which permits counter-pressure between 50 mm. Hg and 300. After application of the brassard the pressure is raised progressively; the needle of the manometer is displaced like the hands of a watch, soon showing slight oscillations which may be ignored. At about 80 mm. Hg, however, in normal cases a sudden sharper and larger oscillation appears, and the figure then indicated on the dial of the manometer is that of the minimum pressure. If compression is continued a zone of large oscillations is observed, followed by diminution of their amplitude and by their final disappearance. The point of their complete extinction is that of maximum tension. The modifications of amplitude can also be studied during progressive decompression after previous establishment of a high counter-pressure. This method, which is used equally with Pachon's sphygmometric oscillometer, presents one considerable inconvenience; in most cases the observer is compelled to fix the maximum tension arbitrarily. Actually, the oscillations of the needle do not appear abruptly; before they become marked there is a zone, sometimes extending over several centimetres, in which small oscillations of practically equal size take place, due, as I have shown, to the circulatory beat at the edge of the brassard in the zone of the limb just above it. To remove all subjectivity from the reading of the result I have modified my earliest apparatus; and at present my "sphygmometroscope" admits of automatically exact measurement of both maximum and minimum tensions.

Apparatus Now in Use.

The apparatus at present in use consists of a leathern brassard 17 cm. wide, lined with two rubber bands, not intercommunicating, but both connected with a compressor and furnished with a delicate manometer of large size. A tap, fitted with a screw, secures it in position, whether inflated or deflated, or half inflated—i.e., the position for record of oscillations—when only the lower band is connected with the manometer. In this way the technique of measurement is rendered rapid and simple. A counter-pressure is first obtained, so that the manometric oscillations have entirely ceased; then decompression is begun, centimetre by centimetre, care being taken to keep the manometer in communication with the lower band only. The highest point at which the slightest oscillation reappears is that of maximum tension, for at that point oscillation can only be due to the blood stream and not to the pressure of blood against the upper edge of the brassard, where there is no counter-pressure. The maximum pressure may thus be read accurately within a millimetre. Minimum pressure is obtained by continuing the decompression; first the oscillations increase, and then are suddenly reduced again; the reading at the latter point gives the minimum pressure.

Consideration of Various Curves.

In this way may be obtained maximum and minimum pressures, pulse pressure, and lastly the oscillometric index, which has recently been applied to clinical work. In this communication only passing reference to its interest can be made; readers are referred to the bibliography. Certain writers have recently attempted to represent by a curve drawn by hand, after examination of the arterial circulation by the oscillatory method, the modifications of the arterial beat shown by the needle, and thereby to establish an oscillometric index and obtain a curve which may be studied at leisure. This curve is generally obtained by taking for abscissa the successive intensities of counter-pressure, and for ordinates the corresponding amplitudes of oscillation of the needle. Harlé (Bordeaux), insisting on the greater interest of a double tracing for purposes of clinical study of the normal and pathological functions of the heart and blood-vessels, has proposed a curve composed of two branches, of which the upper gives the heights reached by the needle above its starting-point, and the lower curve the depths reached below that point. According to Pachon: (1) In the absence of any complicating factor in the artery concerned, the oscillometric index expresses the strength of the cardiac impulse; (2) in the absence of any complication concerning the cardiac impulse, the oscillometric index expresses the vascular calibre—i.e., the state of constriction or relaxation of the arterial vessels. But the clinical application of these data is a very delicate matter, and I only refer to the methods by which they are obtained in order to indicate the direction now taken by research into methods of diagnosis of functional disorders of the cardio-vascular system.

No curve traced by hand can better a direct tracing, and inquiry is now being directed towards the construction of apparatus for graphic expression of the circulation of blood under various counter-pressures. Strohl has made use of a contrivance designed to record the oscillations of a manometric needle under constant conditions and varying pressures, which has enabled him, together with Barré (Strasbourg), to publish curves reproducing the modifications of the arterial beat under the influence of increasing and diminishing counter-pressures, and has provoked interesting discussion on the precise points of fixation of maximum and minimum pressures. But the drawback of this contrivance lies in its clumsiness for clinical use; it is more of a laboratory apparatus. I have now attached to my own sphygmometroscope a recording contrivance: the combined apparatus is neither heavy nor difficult to carry about, and it permits of rapid and accurate registering of variations in the arterial beat, disturbances of rhythm, and maximum and minimum pressure points.

The graphic study rendered possible by means of these apparatus has already roused numerous discussions, notably concerning the points on the curves at which the maximum and minimum pressures are to be recognised. For close consideration of this point, I must refer readers to the works on the subject.

The Study of Hypertension.

The perfecting of apparatus has permitted real and rapid progress to be made in knowledge of hypertension and its consequences. First, definition of

Respiratory Efficiency.

In his Milroy Lectures on Respiratory Efficiency in Relation to Health and Disease, of which the conclusion appears in the present issue, Wing Commander Martin Flack has raised the question of physical efficiency tests and the value of special physical training. The results of his investigations in the Royal Air Force Medical Service are valuable contributions to physiological knowledge on a subject of great practical importance; they have a bearing, too, upon the value of gymnastic exercises as compared with out-door games and sport, a matter in which the medical man takes a personal as well as a professional interest. Dr. Flack's evidence proves that success in respiratory tests connotes general good health and failure to reach a certain standard is evidence of unfitness. But granted that respiratory efficiency is a good test of physical fitness, little evidence has yet been adduced in favour of the view that respiratory exercises, as such, will result in physical efficiency. In the past the Services have produced strong advocates of this view. The expanded pouter-pigeon type of chest has disappeared, to be followed by the Swedish system of physical training embodying so-called breathing exercises, and it is noteworthy that a physiologist of the standing of Dr. Flack should have elaborated a system of ten exercises which, with one exception, are modified breathing exercises. Their author assures us that they are in no way designed to supplant recreational exercise nor to replace more elaborate systems of physical training, but in regard to the latter, Dr. Flack is assured that the exercises will give the correct circulatory and respiratory efficiency.

Examination of respiratory efficiency in animals and man shows that the living organism must be considered as a whole. If life arises from life, there is no beginning of respiration; the so-called tissue respiration of the ovum and spermatozoon passes into the respiration of the embryo and fœtus, and the change from placental to pulmonary respiration at birth has been foreshadowed by the movement of the diaphragm and other respiratory muscles, which can be observed during fœtal life. The new-born infant breathes through its nose, for otherwise it could not suck, and respiratory efficiency is a natural result of the increasing demands of an actively growing body. In a similar way the young child or animal needs no special training of its respiratory system; it develops its heart and lungs in response to the great muscular activity of play, which is a characteristic of the young. Athletes, horses, and dogs are trained by progressive muscular exercise, *and the teaching of trainers has been often in advance* of scientific knowledge, or more correctly stated, their knowledge based upon experience has not been regarded as scientific. We have a right to ask the physiologist what is the true basis for the so-called breathing exercises; there is no apparent reason for taking in more oxygen than the body needs or for discharging an undue amount of carbon dioxide. Unless there is increased oxidation produced by muscular work, the body compensates for forced breathing by a subsequent period of decreased breathing or apnœa. The expansion of the apices of the lungs does not in itself protect against tuberculosis, although progressive muscular work in the open air, by increasing the metabolism, can raise the resistance.

The contest between the advocates of thoracic and of abdominal breathing has not been fruitful of practical result; the healthy body has a way of using the method which the occasion demands. The young boy with mobile chest and thoracic breathing at rest throws into powerful activity his diaphragm directly he runs and needs a greater ventilation of his lungs. Muscular exercise either in the form of work or sport has abolished tight-lacing in women for a similar imperative reason. If the man or woman be engaged in manual labour requiring the fixation of the shoulder-girdle, the chest becomes less mobile and the relative rigidity of the thorax is an advantage. What is the place of respiratory exercises we do not know; they may be justified in special cases of disease, but only the sick need the physician. Biological knowledge agrees with the experience of the trainers of athletes, horses, and dogs, that efficiency is best obtained by progressive muscular exercise, by learning to perform work well by doing it. Out-door work, games, and sport may be expected to give better results than the set exercises of the gymnasium.

The Opening of the Session.

A good send-off, with friends on the quay and a message of greeting and advice from an experienced traveller who has not forgotten his own first voyage, is encouraging to one embarking on such a long and arduous pilgrimage as a medical career, and it is matter for regret that some of the more important schools in the metropolis should have discontinued a formal opening function. The student listens to addresses with diminishing eagerness as he grows more self-reliant; to the experienced worker a lecture is apt to convey less information in a given time than a book. But on his first day the scholar arrives with keen appetite, and a savoury hors d'œuvre may materially affect his appreciation of the solid five or six course dinner which he will have not only to eat but inwardly to digest.

The two addresses which we abstract on p. 771 were excellent examples of their kind. The selection of a medical school, whether dictated mainly by athletics, geographical convenience, examination successes, or family tradition, is to many students a harassing business. Others, a place in the school of their choice having been forbidden them, may start their career disappointed and vaguely suspicious of the school to which they have become attached as a second-best. Dr. A. Abrahams discussed what was to his hearers a burning and topical question, and while the advantages of a big school were explained fairly, the compensations to be found in a smaller one were so convincingly set forth that the Westminster students at least must have come away full of cheer and loyalty to their new school. Dr. Louisa Martindale *was equally helpful on different lines*; she laid down certain guiding principles which the woman student will find the more convincing in that some at least will accord with her inclinations. Dr. Martindale's survey of medical work was wide and her conclusions inspiriting—though to those who are still laywomen the acknowledged ignorance of even senior practitioners may seem depressing. The time for her hearers to recall these words will be the inevitable period of self-sufficiency that follows qualification, and especially the first resident appointment. Medical teaching has lost the pseudo-scientific arrogance of the latter part of the nineteenth century, has become more humble and less didactic, even in hospitals. And in the five years or more before the new students reach maturity as practitioners, we may hope that the efforts now being made to bridge the gap between hospital teaching and the difficulties of general practice may have borne fruit.

certain regions. The dependence of arterial hypertension on local and extrarenal arterial trouble, as affirmed by Teissier (Lyons), does not seem to me to be admissible. Lastly, Huchard, who upheld the connexion between hypertension and renal sclerosis, wished to attribute hypertension to a generalised spasm of the peripheral arterioles—a spasm developed under the influence of retention in the organism of vaso-constrictor poisons owing to insufficiency of urinary excretion. If this mechanism is the most probable, the origin of this spasm has not been attributed by all writers on the subject to the same cause. Besides Huchard's theory—which has in its favour results of experience, for in a very general sense the meatless diet leads to a fall of pressure in hyperpietic subjects—other factors have been invoked. The work of Vaquez and Josué, Widal and Boidin, leads readers to think that arterial hypertension can be provoked in subjects presenting no nephritis, and in subjects in whom it has already been found, by suprarenal hyperplasia, and that even in those cases where nephritis is evident hypertension is only brought about by a reaction of the suprarenal capsules. The action on the organism of adrenalin, investigated by Sergent and Léon Bernard, gives a certain probability to this hypothesis. There are, however, two objections to acceptance of this suprarenal origin of hypertension—first, that anatomical lesions are usually found in the cortical region of the gland, since the medullary region is considered to be productive of adrenalin; secondly, that numerous observations have shown the inconstancy of suprarenal hyperplasia in patients suffering from accentuated hypertension, since it was found to exist in other cases where hypertension had never been manifested. Research into the adrenalin content of the blood of hyperpietic subjects has given such contradictory results in this connexion that it is impossible to draw any other conclusion.

Possible Renal Origin of Hypertension.

Is the kidney itself productive of a vaso-constrictor substance, accumulation of which results directly in arterial hypertension? A non-dialysable and hyperpietic substance has been extracted from the cortical layer of the kidney—i.e., renin—which is found in the renal veins, but the results of this research have not been confirmed in practice. The study of cholesterin content in the blood of cases of Bright's disease—which shows a large increase of this substance—has led Chauffard to consider that there may be a connexion between hypertension and the accumulation of cholesterin in the blood, the latter being considered as a defensive element. The presence in the blood of products of the oxypurins—hypoxanthin, xanthin, and uric acid, which are powerfully hyperpietic—may also, according to this writer, originate modifications of pressure. That hypertension may frequently be associated with chloruræmia or with azotæmia is easily understood once we have admitted its essentially renal origin, but it seems to me that it cannot be derived from these two affections; it is frequently met with separately, representing, sometimes at least, a type apart—hyperpietic nephritis—accompanying the two other groups, azotæmic and chloruræmic nephritis.

The Latent Phase of Hypertension.

Recognition of hypertension can only be made possible by systematic research; in an apparently healthy subject the first phase of its evolution is not betrayed by any functional symptom noticeable to the patient himself; this is the "presclerotic" phase of Huchard, the "latent" phase of Gallavardin. There may exist no functional symptom at all, not even dyspnœa—which nearly always dominates the clinical picture at some stage of the condition—or albuminuria, or disorders of urinary elimination. Radioscopic examination, however, often shows slight hypertrophy of the left ventricle, for it is the heart's effort in face of the demand made upon it which permits this phase of latency or compensation. As to the duration of this phase, the possibility of checking it, and the fatal results of the disease, practical difficulties prevent clear answers being given. Most frequently hypertension, when unaccompanied by any appreciable disorder, and only noted by accident, has doubtless existed for some time; in some cases in the course of acute nephritis, the increase of pressure will be rapid; but in chronic nephritis the slowness of development, the possible arrest of progress in the condition, and the absence of knowledge concerning its onset, render it impossible to make even an approximate estimate of the latent phase. As to a return to normal of a pressure constantly raised for some time, although it is never reported after the condition is clearly established and allied with other signs of renal insufficiency, it is difficult to deny its possibility in cases where hyperpietic conditions have been under observation from their onset.

The Phase of Sclerosis.

To this first phase succeeds another, which is often the earliest to be clinically observed—a phase in which other symptoms of a toxic nature are ranged alongside hypertension; this is Huchard's period of sclerosis. To name only affections of the whole circulation, there arise certain aphasias and transitory pareses, epistaxis, retinal hæmorrhage, tinnitus aurium, and dyspnœa, the latter due partly to mechanical hindrance of cardiac function, and partly to intoxication of the subject. The evolution is variable; and the terminal events which arise from toxic troubles only, or from their association with mechanical disturbances, may be determined exclusively by circulatory troubles, and are then manifested by vascular ruptures due to excess of pressure in vessels previously weakened by the causal malady or by cardiac insufficiency.

Myocardial Insufficiency and Pulmonary Œdema.

Insufficiency of the myocardium appears rapidly or slowly; when rapid there is acute œdema of the lung. In a hyperpietic patient, often apparently healthy but generally presenting aortic insufficiency together with hypertension (type of pressures, 250–100 mm. Hg), a rapid series of sequelæ is disclosed by extreme dyspnœa, pain at the apex of the lung, and characteristic salmon-coloured sputum; at the same time peculiar râles indicate rapid serous invasion of the lungs. This is the crisis of acute œdema, which sometimes results in death in several hours or even in a few seconds, before any help can be given to the patient. But if the patient can be brought through the crisis by therapeutic means, amelioration may be obtained, and the pulmonary sequelæ may die down, sometimes disappearing completely. But later, either with no apparent cause, or following a gap in treatment, or some emotion, the disorder will reappear, more or less rapidly—ending in death, or receding into the background again, but always threatening reappearance, and constituting a chronic subacute form of pulmonary œdema. The progress of the arterial pressure explains these various sequelæ. At the moment of appearance of the earliest sequel the pressure becomes rapidly modified. At first there is parallel rise of maximum and minimum pressures. The maximum is raised from one to two points, the minimum from two to three; thus the cardiac effort becomes much greater. Then the state of pressure is suddenly modified—the minimum falling three or four points, but the maximum even more. At this moment death may supervene, if the maximal depression persists. But with appropriate treatment (first bleeding, then cardiac tonics) the modification may be reversed; the minimum will rise one or two degrees, the maximum two or three; and the patient presents for a time pressures of maximum 180 and minimum 100 mm. Hg. Amelioration becoming more pronounced, the maximum tension may rise again, but never to the figure recorded before the crisis. Then it will once more fall rapidly, perhaps to rise no more, perhaps again to rise a few degrees; by a series of weakening changes it may come about that in a special room. In short, this home for healthy children was conducted as far as possible on the lines prevailing in babies' hospitals, the statistics the following year affording striking proof of the value of the new arrangements. The total mortality rate fell from 20·8 to 6·8, while that among infants in the first three months of life fell from 40 to 7·6 per cent. The number of infants sent to the clinic on account of serious illness was reduced from 20 to 5; a gradual and steady increase in weight was the almost invariable rule, and the last traces of hospitalism among the inmates vanished.

DR. WALFORD'S RETIREMENT.

The city of Cardiff in 1888, now nearly 34 years ago, appointed its first whole-time medical officer of health in the person of Dr. Edward Walford, who had already gained experience in public health administration at Ramsgate. Some estimate of the importance of the work Dr. Walford has carried out in this long period may be gathered from the fact that when he took office the population of the city was about 82,000. It is now over 200,000; during the period the water-supply of the town has been reorganised with, as a consequence, the entire disappearance of enteric fever; a scheme for isolating cases of infectious disease has been perfected with the establishment of the City Infectious Diseases Hospital, while the death-rate of the town, which in 1890 was 21·6, has fallen to a figure of 11·3 at the present time. Dr. Walford has not been allowed to leave the district and retire to live at Walmer without receiving recognition of the signal services he has rendered. On Sept. 24th a special meeting of the Welsh Branch of the Society of Medical Officers of Health, of which he had been president, was held, with Dr. Llewellyn Williams (Welsh Ministry of Health) in the chair. The new president, Dr. Howard Jones (Newport), on behalf of the branch, presented to Dr. Walford as a token of the esteem felt for him by the society a Kew standard barometer and a pair of Zeiss field-glasses. This occasion was not the only one on which Dr. Walford's friends and colleagues gathered to do him honour, for a gathering of over 40 medical men entertained him at a banquet on Sept. 28th, and a further and more intimate reunion took place on Sept. 29th at the City Hall, when Dr. Walford's immediate colleagues, along with present and past members on the staff of the public health department, met to present him with a bureau. Dr. Walford's career is a welcome reminder that it is within the competence of a sanitary officer to administer efficiently without forfeiting the affection and esteem of colleagues in clinical practice.

THE WASSERMANN REACTION IN CONGENITAL SYPHILIS.

In the course of a recent discussion at the Royal Society of Medicine on the diagnosis and treatment of congenital syphilis, Dr. H. Morley Fletcher stated, with fairly general approval, that the problem of the Wassermann reaction was not capable of solution by the clinician, but must be left to the laboratory worker for much further investigation. Other views are also current. Dr. E. Crawford and Dr. G. B. Fleming published in our last issue some additional laboratory findings on the power of certain drugs to convert the Wassermann reaction from positive to negative in cases of congenital syphilis. The authors seem to imply that this deflection of complement constitutes the crucial test of the efficacy of treatment, and that the amelioration of symptoms is of less importance. Thus they found that in a series of 12 children over 1 year of age they were unable to convert the positive Wassermann reaction to negative by means of the drug sulfarsenol administered intramuscularly, although Dr. Leonard Findlay, in his series of 20 children over 1 year of age exhibiting a positive Wassermann reaction, had, by means of intravenous injection of salvarsan or kharsivan, obtained a negative reaction in 50 per cent. of cases. It is, therefore, argued that intramuscular sulfarsenol is not so effective in the cure of congenital syphilis as is intravenous kharsivan. An observation of Mr. J. E. R. McDonagh's, adduced by him at the meeting already mentioned, throws new light on the value of complement-fixation tests in discerning the presence of syphilis in children. He found that in children born of treated syphilitic mothers the Wassermann reaction was, as a rule, negative and might remain so for some years, until clinical manifestations occurred. If the reaction then became positive for the first time at about the age of 3 years, it remained so despite treatment for the rest of the patient's life. Further, when the Wassermann reaction was positive during the first few months of life, even if the child was left untreated, the reaction tended to become negative about the age of puberty. As Dr. Crawford and Dr. Fleming did not give details of their series of children over 1 year of age, it is impossible to say whether or not they fall into the group of cases described by Mr. McDonagh, in which the Wassermann reaction becomes positive a few years after birth, and cannot be influenced by treatment. Should this be so, it is clear that the Wassermann reaction could not be considered as the crucial test of the potency of the drug sulfarsenol to cure congenital syphilis, and that the clinical symptoms must receive due recognition. Such doubts and difficulties are apt to occur whenever laboratory findings are divorced from clinical observations. Thus the absence of tubercle bacilli from the sputum does not prove that pulmonary tuberculosis is non-existent, and bacilli may be found without activity of the disease. The X ray shadows cast by tuberculous pulmonary lesions may be indistinguishable from those due to other pathological conditions. A positive Widal reaction does not necessarily indicate an active infection with the typhoid bacillus. Clinical and laboratory findings are two aspects of a picture, each of which is essential to give it any claim to reality.

CONGENITAL ATRESIA OF THE PUNCTA LACRYMALIA.

Dr. Harry Gradle,[1] of Chicago, who records an illustrative case, remarks that though congenital closure of the conjunctival openings of the lacrymal canals is supposed to be fairly common, comparatively few cases have actually been reported. In Graefe-Saemisch's "Handbuch," von Hippel states that atresia of the puncta with patent canaliculi and normal relations of the remainder of the tear passage has been described, the resultant epiphora being easily relieved by simple puncture of the epithelial covering. Examples of congenital atresia of one or more puncta have been reported by Ferron, Nielsen, Labegne, Bernhardt, and Webster Fox, amongst others. The last-named writer's case is of interest on account of the absence of epiphora for more than 20 years in spite of complete congenital absence of both puncta. The condition is not serious. In the treatment as little as possible should be done consistent with the restoration of function, and slitting of the canaliculi is quite unnecessary. The case reported by Dr. Gradle occurred in a nurse, aged 21, who had suffered from continuous lacrymation of the left eye as long as she could remember. There was no discharge from the eye, and lacrymation was only excessive under very irritating conditions of wind and weather. Examination showed that the right eye was normal in every respect, but that the openings of the puncta lacrymalia of the left eye, which were normally situated, were covered with a thin layer of epithelium. A cure was effected by breaking through the epithelial covering with the point of a Graefe knife, inserting a punctum dilator, and performing lavage into the nose both from the upper and lower puncta.

THE LANCET.

LONDON: SATURDAY, OCTOBER 8, 1921.

Health Insurance and the State.

A DISQUIETING feature of the economy campaign is the indiscriminate use of the knife, the cutting down of all expenditure whether productive or not. Expenditure on the Ministry of Health cannot be regarded as wasteful, seeing that it is intended to create and supply what the former head of one of the fighting services once characterised as the munitions of life. National Health Insurance is described in the preamble to the Acts as designed to provide for Insurance against loss of Health and for the Prevention and Cure of Sickness. No one now disputes that preventive medicine must be linked to clinical medicine for any real progress to be made in public health administration, and with the medical service set up by the Insurance Acts a real start has been made in bringing the general practitioner into the orbit of the Ministry of Health. Those who talk of abolishing National Health Insurance and getting rid of medical benefit also talk no less glibly of decontrolling the doctors. But the control of which they speak is really coöperation: coöperation which raises the standard of medical work and gives new ideals to general practice. Decontrol would spell not liberty but disorder. Medical benefit, as yet in its infancy, is now limited to what is known as general practitioner services, but the demand is steadily growing for further provision such as prompt hospital treatment, including major operations and the advice of specialists.

During the week the attitude of important medical groups has been made known. The executive of the Federation of Medical and Allied Societies has addressed a letter to the Minister of Health asking on reasoned grounds for a careful inquiry into the present working of health insurance before departmental action is taken. The Insurance Acts were an experiment in public health administration, for the success of which no sufficient data have yet been offered. The letter of the Federation refers to the criticisms levelled alike at the methods of the Health Ministry, the administration of the approved societies, and the services of the insurance practitioners: criticisms which may be ill enough informed and yet incapable of being refuted in the absence of exact information. Another gathering of 250 medical men at Birmingham, on Friday of last week, after listening to an address by Dr. ALFRED COX, medical secretary of the British Medical Association, passed a resolution to the following effect: That where it is necessary to organise or provide a general practitioners' service for any section of the community unable to pay the ordinary fees, such service is best given on the lines of the present panel system, and this meeting does wish medical benefit under the National Health Insurance Act to continue, so long as the conditions are such as will allow of a good service being given. Dr. Cox had logically set out the six ways by which medical attendance could be ensured for persons unable to provide it for themselves. Such provision might be made (1) by ensuring that every person willing to work should be paid wages enabling him to provide his own medical attendance by private arrangement; (2) by voluntary charity; (3) by the Poor-law; (4) by the club system; (5) by a whole-time State service open to everybody; (6) by a contributory insurance service. Alternatives 1 to 3 he eliminated at sight. Should contributory insurance be abolished, an alternative would doubtless be to resuscitate and develop the old discredited club system. How unsatisfactory that system was a generation ago is set forth briefly in an article on page 775. Dr. Cox roundly stated that apart from a whole-time State service he could see no practicable alternative to the present system of contributory health insurance. Of this system the fundamental principles were that every doctor had the right to take part in it; that every patient had the right to choose his doctor, and every doctor except in one-man areas to get rid of any patient; that the remuneration was fixed by central bargaining and was the same all over the country; and that doctors collectively had a great deal of control through the panel committees over their part of the system.

The Minister of Health has now formally notified insurance practitioners that after the end of the calendar year a reduction ought to be made in the present capitation fee of 11s. The amount of the proposed reduction has not yet been stated, nor have any grounds been given for setting aside the decision of the arbitrators in March of last year; but there is a risk that any reduction in the capitation fee will be countered on the part of the doctors by a reduction in the quality of their service. At all events, in the words of the Federation's letter, any reduction before full inquiry has been made into past results and future requirements would tend to alienate the goodwill of those practitioners whose coöperation is essential to the success of the service. What we fear is that great numbers of practitioners who have small panels as part of large general practices may resign from the panel when the reduction becomes operative. And it is just the practitioner of experience in good-class practice whose coöperation the State cannot afford to lose. Whatever the ideals of the insurance practitioner—and with few exceptions they are high ideals—the quality of work done must depend ultimately upon the conditions under which service is given. The insistent demand on the part of approved societies is for smaller panels and stricter limitation of lists. A serious reduction in the capitation fee will make this more difficult to secure. With a smaller fee it will be necessary for the practitioner to have a larger list in order to enable him to devote himself to his insurance work. Improve the conditions of panel practice, provide the necessary facilities, and the quality of the service can be guaranteed. It would be futile economy to drive out the best men by reducing the remuneration. The annual Panel Conference, which meets in London on Oct. 20th, is to be asked to reaffirm its opinion that 13s. 6d. is the lowest capitation fee that should be offered for an effective service, while not pressing at present for any increase on the 11s. in view of the serious state of the national finances.

of obscure vision continued for five days, this does not seem particularly probable. From the available evidence it would appear that arterial spasm may in rare cases affect the retina as in Raynaud's disease it affects the extremities, that the attacks of obscuration of vision so caused may be completely recovered from, but may, on the other hand, if the condition is sufficiently prolonged, cause blindness in the affected eye. The causation of the condition remains obscure.

OVARIAN HÆMORRHAGE APART FROM ECTOPIC GESTATION.

In a recent paper read before the Section of Obstetrics, Gynecology, and Abdominal Surgery of the American Medical Association, Dr. Edward A. Schumann[1] of Philadelphia discussed hæmorrhages of ovarian or tubal origin not associated with ectopic pregnancy. Pre-operative diagnosis is rarely possible except in cases in which the patient is undoubtedly a virgin. The clinical picture is that characteristic of sudden intraperitoneal hæmorrhage, variable in amount and usually accompanied by acute pain in one or other iliac fossa, although in a few cases initial acute pain may be entirely absent. Some distension usually supervenes with signs of shock and severe loss of blood, or there may be a sthenic reaction with rise of temperature, moderate leucocytosis, rectus rigidity, and the syndrome of the "acute abdomen." Dr. Schumann described a group of cases fairly common in growing girls, who during one of their early menstrual periods show all the symptoms of intraperitoneal hæmorrhage. He considers that such cases, of which he relates a typical example, are not uncommon and rarely end fatally even without surgical intervention. The hæmorrhage in these cases is probably due to an excess of bleeding from the wall of the mature Graafian follicle in the adolescent ovary without any demonstrable morphological change in the tissues. In this group of cases a pre-operative diagnosis may be hazarded, whereas in the more or less severe hæmorrhage which takes place from the ovary of mature women in whom ectopic pregnancy is a possibility, the diagnosis is extremely difficult. Three types of ovarian hæmorrhage have been described by Wolf—namely, interstitial, follicular and intra-follicular—all of which may occur in the same ovary. Whether a sclerocystic degeneration or a true fibrosis is the cause of the hæmorrhage is a matter of conjecture. Dr. Schumann reports a case of massive ovarian hæmorrhage in a married woman, aged 37, in whom microscopical examination of the ovary after removal showed a marked proliferation of the normal perifollicular vessels with excessive degenerative arteritis of these vessels. He is of opinion that while a certain degree of arterial degeneration is physiological in the vascular network embracing the mature follicle, massive hæmorrhage is never produced by physiological degenerative changes, and when such an accident occurs some pathological process such as a degenerative arteritis will be found responsible.

FORMALDEHYDE-GLYCERINE IN TUBERCULOUS EMPYEMA.

An interesting chapter in medicine could be written on the valuable remedies which have fallen into disuse for some obscure reason, and have been rediscovered years and even decades later, their revival depending not so much on any technical modification or improvement as on the enthusiasm, tempered with discrimination, of its latest sponsor. Many years ago Murphy advocated the introduction of half an ounce of glycerine-formaldehyde solution into the pleural cavity in cases of tuberculous empyema, and though the results were promising, his procedure does not seem to have been adopted in many European hospitals. In the June number of the *American Review of Tuberculosis* Dr. George B. Kalb reviews his experience of 12 cases of tuberculous empyema observed during the past four years. The seven patients who recovered were treated by the following method. All the purulent material that could be aspirated through a large needle being removed, from 1 to 12 ounces of a 2 per cent. solution of formaldehyde in glycerine were injected, the amount varying according to the quantity of fluid withdrawn. Care was taken at the first injection to introduce too little, rather than too much, and never to inject more than half of the quantity withdrawn. Air was then introduced until the manometer showed a pressure near the atmospheric, or, if the case was one of artificial pneumothorax, the pressure was raised to that usually reached in any particular refill. In two days to a week after the first injection the chest was again aspirated, and it was then common to find the contents of the pleural cavity sero-purulent. More formaldehyde in glycerine was again injected and left in the chest for three to ten days. This treatment was continued till the contents of the pleural cavity became sero-sanguineous; being sterile at this stage, the fluid was not aspirated, but left to be automatically absorbed. Each injection was followed by a more or less violent reaction, the temperature rising as high as 103° F., and a sense of pain and discomfort in the chest being provoked. This reaction rapidly subsided, and in two or three days the patient felt as comfortable as before. Murphy, apparently, advocated the introduction of only half an ounce of the glycerine-formaldehyde solution, but in other respects his procedure was much the same as that already described. In his *Clinics* of 1915 he suggested that the formaldehyde-glycerine solution acted by sterilising the pus and keeping up the polymorphonuclear leucocytosis. Dr. Kalb's seven recoveries out of 12 cases are the more encouraging, as several of the patients who died were already in extremis. His material is, however, small, and it would be interesting to learn what the experience is of other physicians who have adopted this treatment in a large number of cases. Billings has reported a death following an injection of formaldehyde in glycerine, but it is doubtful whether this fatality was due to the composition of the injected fluid. In considering such an isolated fatality the physician would do well to bear in mind that there are few drugs in common use the injection of which has not been credited with sudden death.

DIVERTICULUM OF THE BLADDER.

Judging by its absence from the index of current surgical text-books, diverticulum of the bladder is not frequently met with in this country. Mr. Russell Howard in his Practice of Surgery[1] gives a short paragraph on the subject with an illustration of a large diverticulum from the museum of the London Hospital Medical College. According to Dr. Robert H. Stewart[2] of Topeka, Kansas, who records an unusual case, until about ten years ago diverticulum of the bladder was regarded rather as a surgical curiosity than as a pathological condition, coming within the scope of most surgeons' experience. Recent investigations, however, have shown that it is not so rare as had hitherto been supposed. It occurs almost exclusively in the male sex, only a few examples having been observed in women. Two types of vesical diverticulum are encountered. The first, which is found in older subjects, is associated with enlargement of the prostate and urinary obstruction. The second type occurs in younger subjects, without evident prostatism or obstruction, but usually with even more pronounced retention than in cases of prostatism. In either type there may be a single diverticular sac, or there may be one large and several smaller ones. Trabeculation of the bladder wall is generally present. The initial sym-

Annotations.

"Ne quid nimis."

THE GROWTH OF MEDICINE IN CHINA.

LAST month the building of the Union Medical College was completed in Peking. Chinese in external appearance, entirely Western in equipment and internal arrangement, the first great medical school of the Eastern republic is worthy of its purpose and of the generosity of the Rockefeller Foundation which built and endowed it. Some 80 students entered the medical course for the academic year 1920–21, and the numbers can now be largely increased, for there are 90 professors and teachers on the staff. But it is one thing, as the *Review* of the Foundation remarks, to give Chinese men and women a modern medical training; quite another to provide the conditions under which that training can be of largest service to Chinese communities. The chief agency for helping the native practitioner is the Western type of hospital, which aids him in maintaining his ideals and helps to disseminate in the community knowledge of the aims of curative and preventive medicine. These hospitals are for the most part under missionary auspices, and the story of the development of medical missions in China is ably told by Dr. Harold Balme, dean of the school of medicine in the Shantung Christian University at Tsinan, in his book on China and Modern Medicine. (London: United Council for Missionary Education. Pp. 224. Price 5s.) A hundred years ago, as Sir Donald MacAlister points out in his prefatory remarks, no human enterprise could have seemed more hopeless than the physical and spiritual transformation of China. Until a few years ago every occasion of discontent was accompanied by an outburst of anti-foreign feeling, frequently ending in bloodshed, whereas to-day political revolutions are invariably accompanied by proclamations holding the foreigner's life and property of the foreigner inviolate. This has been brought about in the main by the civilising influence of medical missions and the substitution of Western scientific ideas for superstitious Chinese methods. The pioneer of this work was Thomas Richardson Colledge, who founded the first voluntary hospital in China—the Ophthalmic Hospital at Macao—nearly a century ago. Much still remains to be done, and Dr. Balme asks that English and American doctors should visit the hospitals of China and acquaint themselves at first hand with the conditions of life and medical practice there. He very rightly demands the provision of better facilities in Western hospitals and laboratories for the post-graduate study by Chinese medical men and women. China offers special opportunities of medical research, for many pathological conditions occurring there are seldom found elsewhere, and disorders which are common to all lands are seen there in aggravated form owing to long years of neglect. We print on another page the substance of an address on medical missions in China delivered by Dr. Balme during a recent visit to this country.

MORE RADIUM.

A LARGE consignment of radium amounting to about 2 g. of the element has reached this country from the Czecho-Slovak State mines. The mines in question are those at Joachimsthal, from which radium was first separated by the labours of Prof. P. and Mme. Curie. The consignment, which arrived under the personal supervision of Prof. F. Soddy and Mr. Shepperson Wilson, is but the first of supplies which are expected to come for some years from the Radium Corporation of Czecho-Slovakia, whose offices are registered in Prague. This is the result of negotiations with the Imperial and Foreign Corporation of London. It is the intention of the latter body to arrange for supplies of radium to be devoted to the dual services of medicine and of science. Prof. Soddy, who is expert adviser to the Corporation, will be controller of such part of the radium as may be installed in laboratories at Oxford. Further than this, directional offices, possibly developing into an institute, will be set up in London, whereby the aims of the scheme may be secured. If facilities on a large scale are to be provided for the medical use of radium, it is obvious that this should be done in no indiscriminate manner, and the whole of these arrangements will be under medical direction. At the present time a scheme of investigation in radium therapy at various recognised centres in the British Isles has been put into operation by the Medical Research Council and valuable results are anticipated from this coördinated effort. It is safe to predict that further facilities for the use of radium will have an important effect in developing our knowledge upon its uses in disease, provided that these facilities are made the most of. The subject has, happily, passed the stage at which valuable results are looked for from haphazard methods, and it is no disrespect to individual enterprise to state that the interests of radium treatment are now best served by coördinated effort on the part of physicians, surgeons, radiologists, and pathologists. To what extent the needs of medical research, as well as medical practice, are to be served by the new radium service in question we have no positive information, but we trust that such a vital need will be kept well in mind.

HOSPITALISM IN INFANTS.

THE question of the prevention of hospitalism among children in creches has recently been discussed by Dr. Eduard Friedberg[1] of the University Children's Clinic in Freiburg, a particularly favourable opportunity for the study of the question having presented itself in the reorganisation at the end of 1919 of the St. Hedwighaus creche attached to the clinic. During the year 1919, out of the 139 children cared for in the creche, 29 died (22 in the clinic attached and seven in the creche itself), the mortality thus amounting to 20·8 per cent., and exceeding the death-rate in the Düsseldorf hospital, recently published by Schlossmann and favourably commented on, of 17·3 per cent. Dr. Friedberg appends a table showing that the morbidity and mortality rate was greatest in the case of the youngest babies (up to 3 months of age), half of whom had to be sent to the clinic for various forms of serious illness, and 40 per cent. of whom died. The older children came off better, but even in them careful examination brought out the fact that a large proportion showed signs of hospitalism in the form of poor mental and physical development, and even of rickets. This particular year having been unusually free from epidemic disease, including influenza, the medical care of the home adequate and the food good, the high morbidity and mortality rate could only be attributed to the cramped space and consequent overcrowding in the home and to the defective training of the nurses employed. At the end of 1919 an extension of the premises was effected and the creche completely reorganised, among the changes carried out being the setting apart of special wards for slightly infectious cases, as well as for the temporary accommodation of more serious cases pending their removal to hospital: the establishment of a quarantine block for new arrivals; and a careful classification of the children according to age, by which means special care could be lavished on the younger ones, and the more experienced nurses detailed to look after them. The minimum distance between the beds was rigidly fixed at a metre and a half, thus limiting the number of cases admitted; another regulation being that visitors who were restricted to two afternoons a week saw the children of early treatment of carcinoma, too often delayed owing to the very natural dislike of the patient to medical examinations. The terror was often allayed if a woman doctor was available, and if for no other disease than this, the existence of women doctors seemed to Dr. Martindale more than justified. She touched briefly on the pioneer work of medical women, and on their activities during and since the war, and mentioned that in private practice, especially in the provinces, women have worked up enormous practices, and have tried, often in vain, to find partners or assistants to help them in their overwhelming work. She herself prophesied that gynæcology would in the future fall more and more to the task of the woman doctor, just as men's diseases will remain in the hands of men doctors; but was aware that some of her colleagues considered that the future would bring no such change, but that the time would come when all sex distinctions in medical work would be abolished. In this connexion she said that recently in the Women's Factory Department at the Home Office there had been an entire reconstruction: women and men had been appointed irrespective of sex, and worked together, with no specialism even in the kinds of factories visited.

---

[1] Deutsche Medizinische Wochenschrift, Sept. 1st.

Dr. Martindale offered to the student in preparation for her profession the following advice:—

1. Divide your lives roughly into three—eight hours' work (if you take off Saturday afternoons and Sundays it will mean ten hours work for five days). Eight hours for play, meals, and ordinary reading, and some art or music. Eight hours for sleep.

2. Remember that you will not reach anything like your ideal of being an efficient and useful doctor unless you know something of the world you and your patients live in. You must read widely and keep in touch with current politics, current literature and art, and municipal life, especially inasmuch as any regulations to do with public health are concerned. You must remember the importance of good manners, and suitable and pretty clothes, for it is unnecessarily annoying to a patient to have to put up with slovenly and ugly things to look at.

3. Keep before you your goal, which will not be reached unless you remember to train yourselves in—(*a*) Observation; (*b*) Note-taking—honestly dividing your cases into (1) clear cases, (2) cases in which the diagnosis is doubtful, (3) cases in which the diagnosis is impossible; (*c*) Self-reliance and independent thought; (*d*) Discretion and reticence: lastly, a self-control that will teach you, as Sir William Osler used to say, "To have your nerves well in hand," remembering that it is character in the end that will carry you even further than brains.

THE MERITS OF SMALLNESS.

THE introductory address at Westminster Hospital was given on Sept. 30th by Dr. ADOLPHE ABRAHAMS, who took as his subject the Advantages and Disadvantages of a Small Medical School. Dr. Abrahams said he was able to speak with some experience of both types of medical school; one of the largest in the Kingdom at which he received his own clinical education, and one of the smallest, of which he was proud to be a member of the staff. There were certain advantages which the large school can offer and of which the smaller must be deprived. On the social side a large medical school with perhaps 500 students could provide facilities for every kind of sport and recreation, and the smaller the school the fewer these opportunities. While exercise, and not merely exercise but competitive exercise, was of considerable value to the student, Dr. Abrahams said he could not regard with much sympathy the inducement to join a large medical school for its athletic advantages alone. In London a student could find an outlet for his athletic ambitions whatever they might be, and though it might be more convenient in some ways to play games for one's hospital instead of for a club without any relation to the hospital, students deprived of such advantages did not seem to Dr. Abrahams to merit much commiseration. It was in many ways an excellent thing to get right away in one's recreations from one's daily associates, more especially as medical students more than any other class of students were given to grooviness, want of interests outside their work, and a perpetual atmosphere of "shop."

Other elements of the social side of the student's life, such as societies and clubs, called merely for enterprise and enthusiasm on the part of some energetic members, and it was easier to establish a camaraderie in a small community than in a large one.

The admission of women students to certain small schools was germane to the discussion. For the most part the large schools had not yet opened their gates to women students. There had been during the last few years a remarkable increase in the number of medical students. No school, however large, could accept unlimited students, for which reason the more popular of the larger schools had been compelled not only to exercise a particular selection and subject applicants to a sort of competition, but even to refuse a certain number unconditionally. Dr. Abrahams was anxious not to be suspected of a want of gallantry nor to be ruthlessly misunderstood when he said that the smaller schools were not in the same position as the larger schools with the privilege of picking and choosing; and if the latter had had to refuse admission to women students, these had naturally turned to the smaller schools for, he would not say hospitality or shelter, but accommodation. Educational experts consulted by Dr. Abrahams had hesitated to be dogmatic, since the period during which co-education in medicine has been in vogue is still so short, but it had been suggested to him that the distraction from work which social intercourse at a susceptible age was bound to introduce must be counted as an item by no means to be belittled; whether jealousy or emulation arises from an inevitable sex competition he felt quite unable to decide.

On the desirability of the separation of intermediate from final studies, Dr. Abrahams said that assuming that elementary training had been adequate it was of no consequence that it had been provided by those not in touch with the clinical teachers. The translation of the preliminary sciences to an earlier stage so that they became part of general education had been recommended by Huxley, and in 1911 the General Medical Council decided to recognise the teaching of such subjects in approved secondary schools as qualifying for the first professional examination in medicine. In Dr. Abraham's experience there had never appeared to be any special anxiety in clinical teachers to attempt close coöperation with the medical school in its more important office. And surely there was no difficulty to an efficient teacher in extracting from the elementary sciences their proper clinical relationship merely because his environment was separated from that to which subsequently his charges would be committed.

Dr. Abrahams proceeded to consider the clinical training which he considered the really important office of any medical school. While a lecturer could serve 500 students as well as five, and a large audience must act as a keener stimulus than a tiny one, from the student's point of view there might be a very real advantage in listening to one who spoke to him face to face and might become a personal force with a life-long influence. Whereas the compulsory attendance at the performances of an articulate text-book which was so frequently the form taken by a compulsory systematic course of lectures was hated as a wicked waste of time. In actual instruction at the bedside the small school required no defence or justification. The smaller the class the more nearly the teaching approximated to the ideal of individual tuition; the examination pass-lists of the small schools were superior, often remarkably superior to those of the larger schools.

The staff of a large hospital was with comparatively rare exceptions recruited from its own students. To a not inconsiderable extent such appointments became a question of graduation and the selected candidate was not necessarily the best man from the students' point of view. But in the smaller school, vacancies

ACOUSTIC EXERCISES FOR DEAF-MUTES.

A paper, posthumously published, by the late Prof. Victor Urbantschitsch[1] of Vienna, whose death we recorded in our issue of July 16th, gives an interesting account of some of the results achieved by the systematic use of acoustic exercises in a large number of deaf-mute pupils at the Israelitic Deaf Institute in Vienna. It has been found on careful examination that in a surprisingly high percentage of cases believed to be totally deaf considerable residual hearing exists; this may, perhaps, be partly explained by a confusion between an inability to understand what is heard and an inability to hear. The acoustic exercises are begun by the repetition of individual vowels, called into the ear, the first vowels used being generally *a* and *o*, and the other vowel sounds being added by degrees. Words easily understood, such as *Mama*, *Papa*, *Auge*, *Nase*, are spoken slowly and in a sustained voice, the pupil, who is told in advance which word will be used, having to repeat the practice-word in order that wrong hearing impressions may be corrected. The words have in every case to be acoustically memorised. It is important that in the earliest stages the pupil should be trained by the same teacher, later on different voices being used. Practice with musical tones (harmonica, piano, wind and string instruments) to acquire pitch and to recognise melody are important. Prof. Urbantschitsch pointed out that the hearing perception in deaf-mutes is subject to much fluctuation, especially in the earlier stages, and perseverance is needed in spite of apparently discouraging results. "Acoustic-fag" is liable to occur and is a warning to limit the exercises, five- to ten-minute periods several times a day usually being enough in view of the intense degree of concentration needed on the part of the deaf pupil. Emphasis is laid upon the fact that even the acquisition of vowel perception in a pupil who has never heard is well worth while, this resulting in the modification of the normal toneless unmodulated voice of the deaf-mute.

In a much longer and more elaborate paper[2] Dr. Max A. Goldstein develops this theme, paying warm tribute to the work of the late Prof. Urbantschitsch, whom he describes as "perhaps the only one who has persisted in his training of the profoundly or totally deaf child by the acoustic method." After giving a brief review of the literature of this subject, and a classification of nerve-deafness into five groups—each group representing a different pathological process—Dr. Goldstein describes in detail his own application of the acoustic method, this being divided into passive and active education. Much use is made of sound comparison, which, as the writer points out, is a logical form of stimulation, awakening a mental differentiation in the brain as well as a physiological selective differentiation in the organ of Corti. A brief history of six illustrative cases is given, including instances of congenital deaf-mutism, marked improvement being shown in every case after two years of training.

JUBILEE OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

The American Public Health Association will hold its "semi-centennial" celebrations in New York from Nov. 8th to 18th. The scientific convention, to be held from the 14th to the 18th, will be divided into sections of laboratory work, vital statistics, public health administration, sanitary engineering, industrial hygiene, and food and drugs, with special programmes dealing with child hygiene, health education and publicity. Prior to the convention proper there will be demonstrations of the various types of public health activity in New York and its environs—the health department bureau, laboratories, health centres, clinics, and hospitals—in order that the health services may be seen in actual operation, especially those admitting of duplication in other cities. Dr. Stephen Smith, the founder and first president of the Association, is now in his 99th year; he will be the guest of honour at a banquet to celebrate his approaching centenary and the jubilee of the Association. At the beginning of October a historical jubilee volume entitled "Fifty Years of Public Health" will be published, with an introductory description of the earlier beginnings of the science. Detailed announcements and programmes will appear from time to time in the *American Journal of Public Health* and the *News Letter* of the Association, or may be had upon addressing the Association at 370, Seventh-avenue, New York city.

SPASM OF THE CENTRAL ARTERY OF THE RETINA.

Of the various causes of obstruction to the blood-flow in the central artery of the retina, spasm of the muscular wall of the artery is one of the rarest; indeed, some authorities have doubted whether it actually occurs. Ophthalmoscopic evidence on the point must be received with caution, since the apparently visible contraction of the artery or one of its branches, rapidly changing to a normal appearance and synchronising with an obscuration of vision in the affected eye, is a condition which might conceivably be caused by variations in general blood pressure where the inner lining of the arterial wall is so thickened by disease that the usual pressure of the blood from behind is only just sufficient to overcome what amounts to a partial obstruction. Some of the cases of obstruction from spasm which have been reported have probably been of this nature, but others, occurring in patients otherwise in good health, will hardly bear any other interpretation than that of actual spasm. So long ago as 1891 the late Mr. A. K. Benson, of Dublin, put on record one such case where an interruption in the blood column was observed repeatedly to move along the inferior temporal artery towards the periphery of the fundus as far as its bifurcation, and then cease. In 1906 R. A. Lundie recorded a case where the contraction occurred in a single branch, and was stationary until the condition of spasm passed off, the apparent contraction then disappearing. Other cases again have been reported where all the vessels have been observed gradually to diminish in calibre, and after a time to refill, the condition being in some cases accompanied by the œdematous retina and cherry-red spot at the macula, typical of embolism or obstruction of the central artery from any other cause. The most recent case is one reported by A. B. Bruner in the *American Journal of Ophthalmology* for July. A man of 31 had several attacks of loss of vision in one eye lasting for a few minutes. He was seen on the day when the attacks first occurred. Between them nothing abnormal was found ophthalmoscopically, but during them the fundus of the affected (left) eye showed the following striking picture:—

> The nerve and retina decidedly paler than in the right eye; the arteries are all markedly contracted, appearing as mere threads; the veins show entire cessation of blood-flow, the regular venous pulse ceasing entirely; the blood in the veins assumes a granular appearance due to the breaking up of the normal blood-column; in from one to three minutes the flow of blood in the veins recommences, at first slowly, then more rapidly, the venous pulse reappears, the arteries assume their normal calibre and appearance, and vision rapidly returns to normal. During the time of the attack no red spot was seen at the macula.

The attacks continued to occur for five days, during which they were observed with no variation of the ophthalmoscopic picture. At the end of that time they ceased spontaneously, and did not recur. No cause of the onset could be discovered by general examination of the patient, unless an alveolar abscess might be considered such, though, as the affected tooth was immediately extracted and the attacks of the first or at the beginning of the second year. To one brought up in English schools, where the student reaches his first contacts with clinical work and bacteriology simultaneously, this seems at first sight strangely early. It is not, however, difficult to appreciate that the fundamentals of the biology of bacteria and especially the all-important technique of bacteriology can be taught to advantage quite early in the curriculum.

---

[1] The Laryngoscope, July, 1921.

[2] Ibid.

Pathology and Clinical Work.

The temporal relations between pathology and clinical work are thus quite different in America and England. In America the whole of the systematic course is taken before the student does any clinical work: in England the two subjects are begun simultaneously after the break in the curriculum which marks the completion of anatomy and physiology. The result is that in London under present conditions it is very difficult to find time for adequate laboratory work in pathology since the student, once he begins clinical work, very sensibly spends practically his whole time at it; in other centres in this country more time is available since as a rule only about half the day is given to ward work in the first year of clinical instruction. There is a growing feeling that some at any rate of the pathological course ought to be taken before clinical work is begun and this is the first important point in which I think we should do well to imitate American practice, though not to copy it too closely. A general elementary knowledge of, e.g., what inflammation is and what bacteria are and do is as necessary an introduction to the intelligent apprehension of disease as is anatomy or physiology: the case for the pre-clinical study of bacteriology is particularly strong. The end of his pre-clinical period also finds the student in a more suitable frame of mind for the proper reception of the principles of pathology than is generally present during his clinical work. For it is the experience in America as well as in England that when a student comes into real touch with sick people they are apt to absorb his whole interest and it is only as he proceeds further in his course—and often enough not even then—that he realises that what he neglects as intellectual and academic is an organic part of what he welcomes as humane and practical.

But it is very questionable whether the attempt which is made in many American schools to cover the whole range of bacteriology, morbid histology, morbid anatomy, and serology in the pre-clinical period is a satisfactory arrangement. Much anatomy and serology, for instance, are intelligible and of interest only in relation to particular human diseases and have little importance from a purely pathological standpoint—from the standpoint, that is, of the science which could exist if there were no human diseases or medicine or surgery at all. The plan which seems the best and which should not be difficult to carry out is to take "general" pathology and bacteriology in the pre-clinical period and "special" pathology all through the clinical period while the student is spending most of his time studying disease in the living. There is of course no clear boundary between "general" and "special" pathology. Roughly speaking, however, the former consists of those topics which are of importance to the general principles of the science, it may be irrespective of human disease, though by choice in relation to it, while special pathology considers the phenomena which are of moment in relation to the particular diseases which are the concern of medicine and surgery. The theory of tumours is general pathology; the various sorts of tumours of the breast, their nature, frequency, and so forth, is special pathology; the practical difference between encephaloid and scirrhus is clinical pathology. The relation of the animal economy to foreign proteids and the formation of antibodies is general, diphtheria antitoxin is special, the Widal reaction clinical. To recognise the existence of these categories is for the improvement of teaching; to insist upon them is to encourage the current vice of cutting up the curriculum into watertight compartments.

Teaching Materials: Post-Mortem Examinations, Museums.

Specimens in bottles and sections under the microscope look just the same in America as in England, and one's feeling of being at home among their friendly pathologists is encouraged by the fact that the methods of instruction are very much the same as ours—definitely more so than in physiology or medicine. In physiology the American students seem to do more for themselves and to embark on larger and more elaborate experimental observations than ours do; in medicine they are less independent than ours. Two points are worth notice. The study of morbid anatomy is greatly hampered by the difficulty of obtaining permission to make *post-mortem examinations*. The proportion of deaths in hospital which come to autopsy varies much in different places according to the composition of the local population (Roman Catholics, Jews, &c.), the skill and urbanity of the resident medical officers, and the general state of public opinion in the city on the subject; it seldom rises above 60 per cent. and may fall as low as 10 per cent. The disadvantages of this state of affairs needs no emphasis; but it is perhaps not easy for us, who have been brought up on almost universal post-mortems, to realise how great they are. In consequence there is a disinclination to allow the undergraduate student to do the actual work of the autopsy, the reason usually given being that they are liable to make a mess of valuable material. The question of striking a reasonable balance between doing the work in the best possible manner and allowing the student to learn in a real way seems to be generally settled against the student.

The other thing which strikes one is that *pathological museums* bulk much less largely than with us. The post-mortem difficulty is to some extent no doubt responsible for this, but it is chiefly due to the difference in the historical development of medical education in the two countries, for the museum cult in general is at least as highly developed there as here. Medical education and research in England had grown within a measurable distance of their present position before the experimental method began to make any great impress on the biological sciences; under these circumstances it was natural that the methods of Cuvier and Hunter should have a predominant influence, and the extensive collection of specimens from the dead-house was a corollary to the impetus which careful autopsy work was giving to medical science about the middle of the nineteenth century. In America the experimental method was well understood as a weapon of progress before the great reform in medical education began 15 or 20 years ago. The museum at that time had come to be relatively less important, and it had not established itself as one of the chief items of equipment before the interests of laboratory work reduced its comparative prestige. The truth probably is that we attach undue importance to an instrument of instruction that is of less moment than it used to be; in America a useful item is apt to be neglected. It is probably no harm that the form of oral examination, which hinges on the identification of museum preparations, is apparently unknown.

The Cult of Clinical Pathology.

The work which in England is commonly known as "clinical pathology" is pursued in America on a scale and with an intensity which is hardly known with us. In a few places the actual laboratory work is done by the pathological department, as commonly here, and this is more often the case with surgical investigations and bacteriology than with inquiries starting in the medical wards. In the better schools, however, the obvious truth that making a blood count is no more a part of "pathology" than is auscultation with the stethoscope has long since been realised, and the work which with us is done by the clinical pathologist is undertaken by the departments of ptoms are difficulty and frequency of micturition, with a burning sensation. Patients have all the clinical symptoms of severe cystitis. In old cases there may be a kidney infection, and renal insufficiency may be well marked. In some cases the diverticulum may be felt per rectum. The diagnosis of vesical diverticulum which these symptoms suggest is confirmed by cystoscopic and X ray examination. Stagnation of residual urine in a diverticulum favours infection. Calculi, single or multiple, are found in about 15 per cent. Cystitis extending from an infected diverticulum is very common. The mortality is high in cases of diverticulum complicated by carcinoma, calculi, or marked renal infection. The only successful treatment is radical removal of the diverticular sac either intravesically or extravesically. The latter method may be intra- or extra-peritoneal. In the absence of infection the results of operation are very good. In Judd's 44 cases all survived except ten, two of whom died immediately after the operation. In the 34 survivors the functional results were good. In Dr. Stewart's case, which occurred in a man aged 31, the diverticulum occupied the position of the right ureteral orifice and was complicated by a secondary cystitis in which the only micro-organism found was *B. coli*. Until a year ago the patient had been suffering from gonorrhœa of three years' duration. At the time of publication the case had not come to operation.

TRANSFER OF HEALTH JURISDICTION.

BY an Order (1921, No. 958) made under the Ministry of Health Act, four sections of the Factory and Workshop Act, 1901, are transferred from the jurisdiction of the Home Office to that of the Ministry of Health. These sections deal with (Sec. 61) the prohibition of employment of women after childbirth; the (Sec. 97–100) provisions relating to bakehouses; (Sec. 109) making of wearing apparel where there is scarlet fever or small-pox; (Sec. 110) prohibition of homework where there is infectious disease. Section 61 provides that the occupier of a factory or workshop shall not knowingly allow a woman or girl to be employed therein within four weeks after she has given birth to a child. This section was extended to laundries. Local authorities administering maternity and child welfare schemes are asked to assist occupiers of factories, workshops, and laundries in observing the provisions of this section. Under Section 98 the local authority will now have concurrent powers with the factory inspector to undertake a prosecution in the case of a bakehouse which is unsuitable on sanitary grounds. The powers and duties of local authorities under Sections 109 and 110, relating to homework in premises where there is infectious disease, are not materially affected by the transfer.

Dr. John Elder McIlwaine has been appointed to the chair of materia medica and therapeutics in the Queen's University of Belfast, formerly occupied by Sir William Whitla. Dr. McIlwaine, as one of the physicians of the Royal Victoria Hospital, Belfast, has devoted himself largely to the subject of cardiology.

THE LANCET of January 1st, 1921.

THE Manager will be obliged to readers who have not any further use for their copy of THE LANCET of the above date if they will kindly return it to him at 1, Bedford-street, Strand, W.C. 2. The postage on the number is three halfpence. He will be pleased to pay for those returned.

LITERARY INTELLIGENCE. — Oxford University Press announces among its new books from the Yale University Press: "The Dawn of Modern Medicine," by Albert H. Buck; "The Pathology of Influenza," by M. C. Winternitz, I. M. Wason, and F. P. McNamara; and "The Lethal War Gases: Physiology and Experimental Treatment," issued under the direction of Frank P. Underhill.

OPENING OF THE SESSION AT THE MEDICAL SCHOOLS.

MEDICINE FOR WOMEN.

THE inaugural address at the London School of Medicine for Women was delivered by Miss L. MARTINDALE, M.D., B.S., J.P., who began by alluding to recent criticisms made in the press as to the need of women doctors, their capabilities, and the attitude of the public towards them, and proceeded to a brief review of the position of the present woman doctor in Great Britain, her influence on the social and political life of the nation, her relations to the medical profession at the moment, and her place in the scientific, social, and political life of the future.

Dr. Martindale discussed the revolutionary changes in the prevention and cure of disease in modern times. She dealt first with infant mortality, pointing out that the 2000 or more infant welfare centres, the establishment of which had contributed to its reduction, were nearly all staffed by women doctors. She spoke of the maternal mortality of childbirth, practically undiminished since 1881, and of the ways in which this may be combated in the future; also of the need for research into the anæsthetics administered at childbirth. Of the future employment of women doctors in the insurance medical service, Dr. Martindale spoke in hopeful terms.

In the research into the initial stages of disease, now being conducted at the St. Andrews Institute for Clinical Research, Dr. Martindale was, like most practitioners, keenly interested. Speaking from her own experience as a general practitioner, she said:—

> In your hospital work you will be taught the ætiology, the signs and symptoms, the diagnosis, the prognosis and the treatment of the principal diseases that man is exposed to. You will see typical and advanced cases—and learn to recognise these diseases. When you start in general practice you will find to your dismay that many patients will come to you, complaining of feelings of exhaustion, of unfitness for work, of uncontrolled attacks of emotionalism or irritability, of unexplained sensory symptoms. You will examine them as you have been taught to do; you will go into their habits of life, their diet, and so on, and you will probably prescribe a change of air, a daily two hours' rest, and give them perhaps an iron or valerian tonic, and it will not be till later on, when you are collecting your cases together, and trying faithfully to index them according to their diagnosis that you will realise how inadequate your knowledge of the initial stages of disease is, and how inefficient your treatment will have been because you have really been quite unable to diagnose your case. About a year ago I was dissatisfied with my system of records of private patients. I started a fresh card-index, and got my secretary to index, not only according to the names of the patients, but also the diseases they were suffering from—and this was what I found. Of the 3307 cases that I had seen in private practice in consultation only (I did not include those I had visited at home, nor those I had examined in the ordinary routine of school or insurance examination, nor any of my intensive X ray therapy cases) I found that although I had divided those cases under the headings of 327 different diseases, there were still quite a number that were classified under their symptoms rather than their disease. Imagine my relief then when I found that this was the lot of every practitioner, and my interest to find that as an outcome of this experience Sir James Mackenzie had started an institute with the express object of investigating disease before the occurrence of any structural change in any organ of the body, and so providing a diagnosis at a period earlier than is possible by the methods now in use.

Dr. Martindale then described the general scheme of the St. Andrews Institute for Clinical Research, familiar to readers of THE LANCET.

On the question of the treatment of cancer, Dr. Martindale had some hope to offer. She described recent developments in intensive deep X ray therapy, and said that from her own experience in gynæcological X ray work she believed that many of the students of to-day would be radiologists in the future, having under their care many cases of cancer that to-day were still being submitted to surgical treatment. Dr. Martindale pointed out incidentally the importance

Rural Contract Practice.

As an example of the conditions prevailing in rural areas, Dr. S was attending in 1896 the 6000 inhabitants of the village in which he lived and the outlying districts within an area of three miles. In the environs there were lodges of two national friendly societies, a local friendly society admitting both men and women members, and a family club in the nature of a medical aid society giving no financial benefits. The subscription to the last-named was 9*d.* per quarter, out of which Dr. S paid 5 per cent. to a collector. In the village were eight medical aid clubs or societies without adhesion to which Dr. S believed he could not earn a sufficient livelihood; also a National Medical Aid Company which did not scruple to put children on its books for ½*d.* a week. In one case a child was put on the books on a Monday, and died before the week was out, Dr. S's fee for three visits and a death certificate being therefore ½*d.* The club practice was so extensive that 50 visits a day was a frequent programme, apart from surgery consultations. During the influenza epidemic the pressure was so great that Dr. S's health was shattered and he found himself out of pocket. The club members entered without medical examination and paid their medical officer 3*s.* a year; those suffering from tubercle became patients from their first week of membership. No stringent measures were taken to see that subscriptions were paid regularly; a member with lapsed payments could secure another card and present himself as a new member, avoiding payment when in good health. Lists could not be verified and Dr. S was at the mercy of the collectors, for it would have been suicidal to complain. The principal manufacturer of the district, paying £600 a week in wages and £50 a year in rates and taxes, was a member of one of the friendly societies and had to be attended at 4*s.* a year; he suffered from hæmoptysis. Not only the tradesmen avoided paying fees, but also the stewards of both political clubs, the minister of a chapel, one of the churchwardens, and in most cases the wives also of subscribers to medical aid organisations. Club patients governed the vote of guardians and district council, and complaint from Dr. S would simply have resulted in the appointment of a stranger as medical officer of health and Poor-law doctor. In the surrounding villages things tended just as much to the degradation of medical practice.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LTD.—The annual meeting of this society was held at Lincoln House, High Holborn, London, W.C., on Sept. 26th, when the first report submitted since the conversion of the society into a mutual company was adopted. The report stated that the number of policies issued in the sickness and accident fund was 302, for annual premiums of £4318 15*s.* 9*d.* Sickness claims paid amounted to £20,007 3*s.* The total premiums amounted to £41,066 12*s.* 1*d.*, and the accumulated funds amounted to £218,074 6*s.* 1*d.* The number of policies issued under the life assurance fund was 90, assuring £59,005 10*s.* (less re-assurances £10,200) for annual premiums of £1999 7*s.* 6*d.* and single premiums of £1387 7*s.* 8*d.* The claims paid amounted to £1187 10*s.*, and the total premiums amounted to £6365 1*s.* 8*d.* The total premium income of the society amounted to £47.431 13*s.* 9*d.*, and the expenses of administration were £5315 18*s.* 1*d.*, being 11·2 per cent. of the premium income. The chairman, Dr. F. J. Allan, said that as a result of the change to a limited company more business had been done every week than had been done in a month under the old régime. In the sickness fund the new annual premiums were nearly three times the average for the previous year. The ratio of expense only slightly exceeded that of 1919 and some of that expenditure might be regarded as extraordinary and not likely to occur again. There was no other company that could offer such good premiums in all branches of sickness and life assurance. Dr. Knowsley Sibley, who seconded the adoption of the report, pointed out that the society was the only one that issued a permanent contract so that a man once insured remained insured up to the full period. On the motion of Sir William Willcox, Dr. Harvey Hilliard, a retiring director, was reappointed, and Dr. Charles Buttar was elected in the place of Mr. E. M. Corner, who has retired on account of ill-health. The report is more than satisfactory.

Public Health Services.

PANEL REPRESENTATION IN PARLIAMENT.

THERE is a trust fund under the control of the British Medical Association known as the Medical Representation in Parliament Fund. Panel committees have subscribed to this fund in varying amount, Manchester with £200, Devon with £42, and York with £33 at present heading the list. The trustees of the fund hope to support at least two candidates of differing political colour, but the income so far does not justify more than one candidature. The trustees have recognised and are supporting Dr. H. B. Brackenbury, whose services to insurance practitioners are well known. He is believed to have a reasonable chance of success.

HEALTH INSURANCE IN IRELAND.

The threatened division of the Insurance Service between Northern and Southern Ireland is exercising the minds of the Approved Societies Association in that country. The chairman of executive of the Association described the working of the Insurance Act in Ireland as "a service of social reform which had ameliorated the condition of hundreds of thousands of workers . . . . and had materially assisted . . . . in restoring them to health and earning capacity." It was resolved to ask the Irish Insurance Commissioners to accede to a unanimous desire on the part of the approved societies to continue as at present at least until December, 1923.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Belfast.

THE annual report of Dr. H. W. Bailie, medical superintendent officer of health, for the year 1920 has just been issued. It is a full and comprehensive document and affords ample information upon all questions of health and sanitation. The population, as estimated by the Registrar-General to the middle of the year, was 413,000, an increase of 12,000. The birth-rate was 29·4, an increase of 3·7. The death-rate from all causes was 17·5, from zymotic diseases 1·5, and from chest affections 5·6 per 1000. There has been a decrease of 0·4 per 1000 of the population in the death-rate from all causes, and of 1·0 from chest affections. The deaths of children under one year old were 132 per 1000, an increase on the preceding year of 19 per 1000. The notifications of infectious diseases were 2689, a reduction on the previous year of 699. The zymotic rate has shown a progressive decline since the year 1901, when the rate was 3·3 per 1000. In the quinquennium 1901–5 the rate was 2·6 per 1000; in the next two quinquennia the rate was stationary at 2·0 per 1000; in the last quinquennium the rate was 1·5 per 1000. The improvement is largely due to the progressive decline in the incidence of typhoid fever, which was formerly very prevalent in Belfast, but which has now reached moderate proportions. The total number of cases of typhoid fever was 199, an attack rate of 0·48 per 1000 of the population. The deaths numbered 34, equivalent to a case mortality of 17·1 per cent. A large number of cases were traced to infected milk-supply. In 22 cases a history of having eaten shell-fish previous to the onset of illness was obtained. The report states the high death-rate from diphtheria, a case mortality of 16·5 per cent., could be considerably reduced if prompt action were taken to have all cases of throat trouble examined and treated. In many instances the cases are too far advanced before coming under medical treatment. There were 62 cases of puerperal fever with 39 deaths, equivalent to a case mortality of 62·9 per cent. Careful inquiry was instituted regarding the relatively large number of cases of the last-mentioned disease, and precautions were taken. Infection was in several cases traced to nurses, the mortality being least in cases treated on the staff occurred but seldom and few students were willing or able to wait for them. Thus in the open competition for these appointments no sentimental motives swayed the electors, and candidates must supply evidence not only of professional capacity, but of ability and willingness to teach. The larger school indeed suffered in this way from tradition, the members of its staff were speaking generally of a type, a highly desirable type, but there was small chance of penetration by the different ideas and ideals of other schools. Moreover, the newly elected member of the staff was likely to be a younger man than his colleague who joined the staff of a larger hospital.

> Few there are who can aspire to Kipling's exhortation to wait and not be tired by waiting, and to reach a hospital staff after many years of professional experience is not to find oneself in the best condition in which to apply oneself to the requirements of the elementary student. I think, too, the man of great experience—invaluable, of course, to the more advanced student—is not always the best teacher of the rudiments of clinical medicine and surgery. One may regard the pitfalls of diagnosis, the mistakes against which the elementary student must be warned, as the ruts over which the inexperienced traveller stumbles, the recollection of which will be more vivid to the younger specialist still sufficiently footsore to be wary than to the smoothly travelling automobilist whose comfort obliterates all memory of the weary pedestrianism of his youth. The student must be helped to pass his examinations. I can remember a most admirable teacher at my own medical school, a man who taught us no examination surgery, but the practical details of handling patients and patients' relatives. We whom he taught are indescribably grateful now for his invaluable instruction, but we took longer to qualify than our colleagues, and I am afraid did not appreciate him at the time, for we felt that our real education might legitimately begin after we were qualified, and that until we were qualified we were at too great a disadvantage to listen to him without restlessness.

Dr. Abrahams claimed as another advantage of the small school that a resident appointment, the value of which could not possibly be over-estimated, was so much less difficult to obtain. He spoke also of the greater facility of coördination, and of the more balanced allocation of duties to clinical clerks and dressers. The inducement offered by the tradition was not monopolised by the large school. There was no school throughout the kingdom which had not famous sons. Naturally, the larger the school the larger its list of celebrities; but we ought to remember that the school should be measured by its average, not by its exceptions. In conclusion Dr. Abrahams said :—

> I have attempted to represent to you without bias, so far as the absence of bias is possible, the pros and cons of the small medical school. I am sure that you will have sympathised with me in that although I have attempted fairly to look at the matter with unprejudiced eyes my inclination has been towards championship of our smaller medical institutions. And not from merely sentimental motives, for the problem must be squarely faced when so important a question as choice of an alma mater is under consideration. It is a question, too, of direct competition, not one of a small inferior institution in contrast with a large admittedly superior one. The large school must always make a strong appeal, so much so that the whole subject at first blush is one for dismissal with the cynical conclusion that it demands no more argument than would be necessary in the case of a debate upon the relative advantages and disadvantages of a small income. Yet even that subject cannot be summarily dismissed if one may judge by the appearance, far from self-satisfied, and the public pronouncements, far from enthusiastic, of the wealthy. Rarely, indeed, in anything can there be unqualified advantages, and I hope I have been able to show that there is so much to be said in favour of the small school that I may in all sincerity congratulate you upon the choice which you have made.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON, W.C.—A course of lectures, free to medical practitioners, will be given at the hospital on Thursdays, at 1 P.M., from October to December. On Oct. 13th Mr. O. L. Addison will lecture on Acute Infections of Bone. Subsequent lectures will be announced in our Medical Diary. Clinical instruction is given by the members of the staff at their visits; fees for three months' attendance are £5 5s., and for perpetual attendance, £10 10s.

NOTES ON THE TEACHING OF PATHOLOGY IN AMERICA.

BY A. E. BOYCOTT, M.A., D.M., F.R.S.,
GRAHAM PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON.

BY the kindness of the Rockefeller Foundation I was able to spend some time in the spring of this year in studying the practice of medical education at the leading schools in the United States and Canada. The visit was extremely instructive, and one learned a great deal from what high ideals and pretty ample resources have been able to accomplish there by way of reforming the preparation of medical men. And along with a good many lessons in what to imitate, one learned a few in what to avoid.

Differences in Curriculum.

Leaving aside for the present more general matters, I want here to note a few points in connexion with my own subject which appeared to me specially useful. To make them intelligible, however, it is necessary to summarise briefly the differences in the general arrangement of the curriculum there and here. The "medical course" lasts four years, and it begins with anatomy. Chemistry, physics, and biology must be taken in a "pre-medical course," which is required to be of at least two, and sometimes four, years' duration in a university. Roughly speaking—and it will be understood that the details vary in different places and that no general proposition is true of all—the first two years of the medical course are occupied with anatomy, physiology (including biochemistry, which is treated amply), pharmacology and pathology, the third year with didactic clinical teaching and the fourth with practical work in the wards. Compared with our curriculum, relatively more time is given to laboratory work and less to actual contact with sick, a defect which is being widely recognised, so that a year's work as resident ("intern") is everywhere customary among the better men and in some places compulsory. The course is evidently longer than ours, the minimum being six years, the maximum nine. The university degree, which is reached at the end, does not give a qualification to practise which must be obtained from the relevant State Board. The number of students taken in each year is rigidly limited at all the better schools by selection from a considerably larger number of applicants.

Pathology is studied in the second medical year. The relations of bacteriology to the rest of the subject are various. In some places they are united as commonly in England, while in other schools they have separate departments and staffs. Local opinions differed as to which arrangement was the better, but they were tolerably unanimous that it was desirable that the two topics should to a large extent be taught as one—e.g., that the student should study the pneumococcus at the same time as he studies the histology of acute lobar pneumonia. This can be achieved either by taking bacteriology as a subsection of pathology or by an amiable coöperation between separate organisations; in the latter case sufficiently divergent ideals or incompatible personalities may cause considerable difficulties. The nominal arrangement which exists in Manchester and some other English schools whereby the "professor of bacteriology" teaches public health students, while the "professor of pathology" teaches bacteriology along with the rest of pathology to medical students, was not met with; schools of hygiene are at present quite rare in America. Bacteriology, whoever teaches it, usually precedes morbid anatomy and histology, a sequence which is undoubtedly the best suited to the preceding and succeeding subjects of the curriculum. It is sometimes taken early in the first year and not uncommonly along with physiology towards the end solution for varying periods according to whether the finished article is to be a 10, 20, 30, or 40 day gut. The catgut is then dried and wound into hanks supplied in cardboard boxes ready for "surface sterilisation" by any of the well-known methods. If preferred, the gut can be supplied in carbolised alcohol in sealed glass tubes, fully sterilised and ready for immediate use.

The most meticulous care is exercised in obtaining a reliable as well as sterile suture material. Thus every strand is tested at several points in its length both for tensile strength and evenness of diameter; and those which vary by any appreciable amount are rejected. When handled the catgut was found to be smooth, even, pliant without being limp, and of unusual strength. The surgeon can also rely on the gut lasting in the tissues for the required time, since the hardening process is the result of several years' experiment in man. It should be mentioned that the figure in days refers to normal adult muscle. Thus a 40 day catgut remains unabsorbed for just 40 days in muscle; in the peritoneum it is found to last about half that time, and when exposed to human digestive juices, as in the inner suture layer of a gastro-jejunostomy, only about 10 days.

A demonstration of the Souttar needle already described in THE LANCET was also given. The principle has now been applied to curved as well as straight needles, both of the round-bodied and cutting varieties, and mounted with various suture materials. Difficulty was experienced in obtaining an alloy for the shank that would "stand up to the work" on a curved needle, but it is believed that this difficulty has now been overcome.

The catgut and Souttar needles, the patent for which is owned by the London Hospital, are both marketed by Messrs. Allen and Hanburys by arrangement with the hospital, which receives the profits from the sale.

BRITISH ORTHOPÆDIC ASSOCIATION.

A CLINICAL meeting of the British Orthopædic Association was held on Oct. 1st and 2nd at the Shropshire Orthopædic Hospital, Oswestry. This hospital has recently removed from its well-known position at Baschurch to these larger quarters. On Oct. 1st Sir Robert Jones gave a clinical demonstration of a number of cases under treatment in the wards, including rickety and paralytic deformities and cases of tuberculous disease. Mr. Naughton Dunn demonstrated his stabilising operation for the treatment of paralytic deformities of the foot, the principle of which is that in severe cases of paralysis of the foot the deformity is corrected by a bone operation, which includes the removal of the cartilage surfaces from all the tarsal joints, so that these joints become fixed, leaving a foot which moves at the ankle-joint as a simple hinge. All the anterior muscles are thus left as pure dorsi-flexors of the foot, and the posterior muscles are transplanted into the tendo Achillis to act as plantar-flexors. Mr. G. R. Girdlestone demonstrated a method of treatment of Pott's disease carried out in the hospital, and showed a number of cases which had been treated by bone transplantation. Mr. D. McCrae Aitken demonstrated a method of correction of severe kyphosis and of scoliosis on the Abbott's frame. In the afternoon visits were paid to after-care centres, a number of which have been established throughout the county of Shropshire. The children under observation or treatment attend one day in each week, preferably on market day. They are seen weekly by the visiting nurse and once a month by a medical officer from the Orthopædic Hospital. Records, including photographs and plaster casts, are kept at the after-care centres, measurements for splints and appliances made, and simple plaster cases applied at these centres. On Oct. 2nd a series of operations were performed—namely: (1) Albee's operation for spinal caries, by Mr. Girdlestone; (2) osteotomy for mal-union of fracture of the femur, by Mr. Aitken; (3) stabilising operation upon a paralysed foot, by Mr. Dunn; (4) correction of a club foot in a child of 7 with the wrench, by Sir Robert Jones; (5) Souttar's operation for displacement of the anterior superior spine of the ilium as a means of correction of flexion of the hip, by Mr. Noble.

Correspondence.

"Audi alteram partem."

A MEDICAL SUPERANNUATION FUND.

To the Editor of THE LANCET.

SIR,—The formal notice from the Ministry of Health as to a reconsideration of the remuneration fee brings again an opportunity for the establishment of a superannuation and insurance fund for all doctors working under the National Insurance Act. This fund should form an integral part of any agreement between the Ministry and the panel committees. With an elastic scheme of benefits all possible contingencies could be dealt with. Existing insurances, the problems of varying size of lists, and the varying ages of the doctors, could, with actuarial assistance, be fairly and adequately met. Surrender values could easily be arranged for doctors leaving the service, changing their type of practice, or going abroad. Most important of all, the disaster of unexpected broken health could be generously dealt with by the committee of management of such a fund.

In 1913 such a scheme was suggested, and the late Sir George Hardy kindly helped to draw up certain tables. In 1919–20 the London Panel Committee passed resolutions in favour of a scheme for the establishment of a pension fund, and Dr. Addison expressed himself in favour of the principle. Now, again, an opportunity presents itself, and it is to be hoped that panel committees throughout the country will support the principle and leave the details to be formulated by the Insurance Acts Committee and the Ministry. Surely the medical profession cannot be so blind as to fail to realise the immense advantages to be gained under such a scheme. I am, Sir, yours faithfully,

H. H. MILLS.

St. Mary Abbot's-terrace, W., Oct. 3rd, 1921.

INQUIRY INTO THE INSURANCE ACTS.

To the Editor of THE LANCET.

SIR,—The executive council of the Federation of Medical and Allied Societies trusts that you will publish the following memorandum, with postscript, sent this day to the Minister of Health. It is the result of deliberations extending over the past four months and I am instructed to state that other medical societies wishing to add their support may do so without obligation.

To the Minister of Health,

"We, the undersigned duly appointed representatives of organisations coöperating in the Federation of Medical and Allied Societies (Inc.), being influenced solely by a desire to promote the health and contentment of the people with whose physical well-being we are intimately concerned, request the Minister of Health to consider the advisability of setting up an independent committee to take evidence in public, inquire into, and report concerning the working of the National Health Insurance Acts.

"The following reasons appear to justify this request:—

(1) The Acts were introduced as an experiment in public health administration and have been in force for over nine years. Yet no sufficient data are available by which to judge of their efficiency or inefficiency. Neither is it possible to estimate to what degree, if any, they have tended to raise the standard of national health.

(2) Criticisms, often ill-informed but none the less damaging to the smooth working of the Acts, are made of the Health Ministry's methods, of the administration of the approved societies and of the services the insurance medical practitioner provides.

(3) The Acts authorise certain medical services only and these, with the advance of knowledge in preventive and curative medicine, fall short of providing the insured with all that modern medicine has to give.

medicine, surgery, obstetrics, &c., as the case may be. This is an arrangement which it is difficult to value too highly from the student's point of view. No intelligent student will take what the pathologist tells him about medicine or surgery very seriously in comparison with what he learns from his clinical teacher. Since definite clinical pathological laboratories staffed by pathologists have been developed (mostly in the last 20 years) it has been consistently impossible to bring conviction to the student that observations made there are really just as much a part of genuine practical medicine as those requiring no special apparatus which he makes in the wards, that they are subject to the same sort of error, and require the same common sense in interpretation. The position has been aggravated by the fact that his clinical teachers have not always been able to form a critical estimate of the laboratory findings or to place them in their proper relation to the other data from which the diagnosis has to be deduced; the exaggerated respect of some has been as much misplaced as the contemptuous indifference of others. The laboratory work has in consequence been too often looked upon by the student as something curious and remote, possibly interesting, but of no particular concern to him as a practical doctor. In America the bulk of the routine "clinical pathology" is done as a matter of course by the residents; in the most highly developed institutions wards and laboratories form one department under the same head, and those who work in the laboratories are also in charge of patients in the wards. If laboratory examinations are of any value in practical medicine and surgery there can be no doubt that this arrangement is a great advance on our English plan. It achieves a unity of purpose, effort and result which can be obtained in no other way, and it is much to be hoped that in one form or another it will be widely adopted with us.

The advantage is not wholly with the clinical subjects. For if the rise of "clinical pathology" has not done so much harm to pathology as it has done good to medicine, it has done a good deal of damage by deflecting the minds and energies of pathologists from the science which they profess to its technical applications. If "clinical pathology" can be attached to its proper clinical sphere pathology will be the more free to make the genuine progress which lies open to it as a great branch of biological science. The activities of clinical laboratories in America include a good deal of work which in our curious terminology we should call "physiological." The problem of "bringing the physiologist and pathologist to the bedside," about which we have heard so much in recent years, is in this way solved. In America, at any rate, there is no insuperable difficulty in finding men with adequate training in laboratory methods whose real interests are clinical. It is not necessary to bring them to the bedside; they would go there any way.

CONTRACT MEDICAL PRACTICE:
CONDITIONS A GENERATION AGO.

THE conditions of contract medical practice have altered profoundly within the experience of many still in practice, and it may serve a useful purpose to recall briefly the state of affairs as it presented itself to the Special Commissioner of THE LANCET 25 years ago. He observed and inquired, recording what he saw and heard without hastening to point morals, but it then seemed clear to an impartial mind that, while schemes to secure medical attendance at low rates might be praiseworthy in aim, and while it did not necessarily imply disgrace to be medical officer to a medical aid association, nevertheless the schemes were unworthy if they involved oppression of other poor people, and were mismanaged if others than the truly necessitous received benefit from them. The following examples are taken from our Commissioner's experience, names of localities being omitted as no longer relevant.

Urban Medical Clubs.

In the year 1896 an area in a county town with a population of 50,000 was worked by two medical clubs, a Medical Institute and a Friendly Dispensary, about 20,000 of the inhabitants obtaining medical attendance through these clubs at reduced rates. The resident medical officers, though debarred from private practice, did not receive the whole of the money earned by their exertions. Thus in the latest completed year for the 4889 members of the Institute there were 24,173 medical consultations, 34,431 prescriptions were given, and 6934 visits were paid; for this medical aid £980 was collected from subscribers, of which only £384 reached the hands of the medical officers. Dispensers received £116, cab fares absorbed £65, drugs £161, and £32 was allotted to administration. But the remaining £231 was pocketed by the Institute in spite of a stipulation that no profit should be made out of the medical men. In the same year the Dispensary had 4398 members requiring 16,763 consultations, 27,255 prescriptions, and 7815 visits. Of the total receipts, amounting to £917, the three medical officers got only £478, a net profit of £134 being made by the Dispensary. To produce this profit the medical men in the service of the society were giving consultations and advice at an all-round average of 4½d. a time. All classes of the population were invited to join these institutions, and the medical officers had to attend wealthy tradesmen and others in a large way of business as well as those who had retired in affluence. The rate of subscription was 3s. 6d. per annum with an addition of 8s. for wife and any number of children under the age of 16. In the year mentioned 36 medical practitioners in the town agreed to ask that the capitation fee for members with an income exceeding £1 a week should be raised to 4s. 4d. per annum with 5s. for wife and 4s. 4d. for each child, not more than four children in any one family being charged for; further, that no member should be admitted with an income from all sources of more than £2 a week or a higher rental than £20; that extra fees should be chargeable for minor operations, confinements, vaccination, and examination previous to admission; and that the medical officers should receive the whole of the above fees after deduction of legitimate expenses. The medical clubs rejected these conditions and a Medical Protection Fund was started to maintain the medical officers who resigned in a New Provident Association.

Exploitation by Individual Speculators.

At the same period in a Midland city, medical men seemed so incapable of attending to their own business that laymen came to their assistance, naturally pocketing a large share of the profits as a reward of their greater organising capacity. The Medical Aid Association was conducted by a Mr. X, with the help of 40 or 50 house-to-house canvassers; he received for each patient 1d. a week or 4s. 4d. a year, paying the surgeons 3s. a year per member. In practice, however, the whole of this not very generous capitation fee did not reach the doctors, as 2 per cent. was deducted from the account for unexplained reasons, and the fees paid by the many members lapsing without completing a quarter went into the employer's pocket. Mr. Y was the proprietor of a Medical Self-supporting Society to which upwards of 2000 members contributed weekly 1d. apiece, making himself responsible for the payment of quarterly fees to the doctors. In this institution there were, to use Mr. Y's own words, no officers, no committee, no medical staff, no drug stores, no heart-burnings, no jealousies—only, in fact, Mr. Y himself. The doctors received their cheques regularly, but an income of £14 a quarter was the utmost to be obtained in Mr. Y's service, any request for explanation of the amount being met by the production of a perplexing array of figures. Medical officers were, however, freed from complaints on the part of patients, for Mr. Y was prepared to defend his employee against a customer just as a shopman would argue the excellent quality of his goods against a fault-finding purchaser.

dissecting room. The student is supposed to come to the dissecting room with knowledge of the laws and principles of mechanics; in the dissecting room this knowledge is taken for granted, and its application to the structure of the human body, so far as limits of opportunity permit, is brought to his notice there; when he passes on into the hands of the clinicians it surely becomes a part of their business to show him what happens when the normal state is upset, for they must take for granted that he is acquainted with the normal by this time. It is no part of anatomical teaching in the intermediate years to deal with the results of injuries, though demonstrators in the dissecting room frequently point a moral, and, we hope, adorn a tale with some reference to the bearing of their point on some clinical state not beyond the comprehension of their hearers. The teaching of "surgical" anatomy" would appear to be at fault. This unfortunate subject is mainly unfortunate in that it has been put into a compartment with a label of its own, nobody's child and everybody's whipping-boy, instead of running through the whole teaching of surgical diagnosis and treatment. One more point strikes me as calling for protesting comment in this matter: Is it fair to blame the teachers of his youth for the shortcomings of the mature practitioner? Surely a middle-aged man who fails to recognise what has happened in a large way to certain large bones about the ankle cannot be justified in saying that the fault lies with those who tried to instil principles into him 30 years earlier. If their pupils are never to develop their thinking minds, the ways of teachers will indeed be unhappy. But the main thing from the teachers' point of view is to insist on the application of anatomical mechanics to the understanding of injuries and disease being taught by the surgeons from day to day, and not left to the anatomists who may not have the experience, and certainly do not possess the material, to carry it out properly.

I am, Sir, yours faithfully,

Oct. 3rd, 1921. TEACHER OF ANATOMY.

CITY OF LONDON MEDICAL BOOK SOCIETY.

To the Editor of THE LANCET.

SIR,—Our unpretentious but lively little Society can now claim the distinction of having been in continuous existence for a hundred years. We possess the original minute-book recording the foundation of the Society by 20 general practitioners at a house in Frederick-place, Old Jewry, in September, 1821. The number of members is limited to 20, there is no subscription, fines for unpunctuality in forwarding books and for other misdemeanours provide a sufficient income, and, at the end of the year, the books are sold to the highest bidders among the members. An annual dinner is held, and failure to attend involves a fine equal to the cost of the dinner, so that we generally have a full gathering. We claim to be the oldest medical book society in the kingdom. This year the Centenary Dinner (Dr. A. T. Davies in the chair) is to be held at the Abercorn Rooms, Great Eastern Hotel, Liverpool-street, at 6.30 for 7 P.M., on Oct. 25th. All old members will be welcome if they will kindly intimate to me their intention of being present.

I am, Sir, yours faithfully,

ERIC BAYLEY.

21, Finsbury-square, E.C.2, Oct. 4th, 1921.

HISTORY OF BIOLOGY AND MEDICINE.—A course of lectures on the History of the Biological and Medical Sciences from the Earliest Times till the Seventeenth Century will be given by Dr. C. Singer at University College, Gower-street, London, on Thursdays, at 5 P.M., beginning Oct. 13th. A further course, bringing the history from the seventeenth century to the present day, will be given by Dr. Singer in the New Year. The lectures will be illustrated by lantern-slides. The fees are £1 11*s.* 6*d.* a term, and the course is open without fee to all students of the college.

The Services.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. and Bt. Col. E. E. Powell relinquishes the actg. rank of Col.

Maj. A. G. Cummins retires on ret. pay.

REGULAR ARMY RESERVE OF OFFICERS.

G. T. Baker, late Capt., R.A.M.C., to be Capt.

TERRITORIAL FORCE.

Maj. T. W. Banks, having attained the age limit is retired and retains the rank of Maj., with permission to wear the prescribed uniform.

Capt. F. W. C. Brown resigns his commn. and is granted the rank of Maj.

Capt. J. Kinnear (late R.A.M.C. Spec. Res.) to be Capt.

Capts. D. H. MacPhail, A. D. Downes, A. M. Stewart, and L. Beesley resign their commns. and retain the rank of Capt.

ROYAL AIR FORCE.

Dental Branch.—Flight-Lieut. G. Packham relinquishes his temporary commn. on ceasing to be employed, and is permitted to retain the rank of Capt.

THE MILITARY CROSS.

The King has approved of the Military Cross being given to Capt. Atul Krishna Kar, I.M.S., attd. 28th Punj., I.A., for distinguished service in the Field with the Waziristan Force, India:—

"On April 10th, 1921, during the action below Haidari Kach, this officer was sent out from camp to bring in wounded. All ranks of the regiment testify to his devotion and personal disregard to danger while binding up wounded and despatching them to camp under a heavy fire. Owing to his coolness and splendid organisation the wounded were systematically evacuated in very difficult circumstances."

DEATHS IN THE SERVICES.

Lieut.-Col. F. P. Maynard, I.M.S. (retd.), who died on Sept. 30th at Audlem, Cheshire, entered the Indian Medical Service in 1887 and afterwards became professor of ophthalmic surgery in the Medical College, Calcutta, and ophthalmic surgeon to the College Hospital. He was also surgeon superintendent of the Mayo native hospital. He had held the position of assistant editor of the *Ophthalmic Review*, published in London, of *Ophthalmology*, published at Seattle, and of the *Centralblatt für Praktische Augenheilkunde*, and published a "Manual of Ophthalmic Operations."

BIRMINGHAM DOCTORS AND THE PANEL SYSTEM.—A general meeting consisting of about 250 medical men was held on Sept. 30th under the auspices of the Birmingham Branch of the British Medical Association to hear an address by Dr. Alfred Cox on the National Health Insurance System. Dr. Thomas Wilson presided. Dr. Cox referred to the rumours that the remuneration of the insurance practitioners was to be reduced, and that the medical benefit part of the Insurance Act might even be abolished. He thought that the medical profession, after an experience of eight years, should say whether it believed it would be in the interest of the public and of the profession to drop the medical benefit or not. The national insurance system had not had a fair chance. It was born and spent its infancy in an atmosphere of politics and professional prejudice and fears. Then came the war and upset many of the calculations upon which it had been based, and made it impossible to introduce those developments which normally would have been introduced. Now attacks were made upon it by a large section of the press and by politicians in the interest of economy-at-any-price. Dr. Cox had no hesitation in saying that, with all its drawbacks and defects, the system was a great improvement on the conditions existing before the Act was introduced. It had given many working people access to medical treatment which they never had before except as a charity, and it gave the doctors payment for much work which they had previously done for nothing. The following resolution, proposed by Dr. H. G. Dain and seconded by Dr. T. M. Tibbetts, was carried unanimously:—

> Where it is necessary to organise or provide a general practitioner's services for any section of the community unable to pay the ordinary fees, such service is best given on the lines of the present panel system; and this meeting *does* wish medical benefit under the National Health Insurance Acts to continue so long as the conditions are such as will allow of a good service being given.

in hospital. In the late spring and early summer there was a fairly widespread epidemic of encephalitis lethargica, but precise information is not available. Of 9 cases admitted into the Purdysburn Fever Hospital 2 died, 5 were discharged completely cured, and 2 after a prolonged stay in hospital had not completely cleared up on discharge. Considerable progress was made during the year in the treatment of venereal diseases. Clinics are available at the Royal Victoria Hospital, the Mater Hospital, and the Union Infirmary. Salvarsan or its substitutes are supplied free of cost under certain reservations to medical practitioners; and the assistance of the pathologist or one of the medical officers from any of the established centres for consultation, or the taking of specimens for examination, and for carrying out the treatment is available. 3522 Wassermann tests and 484 microscopical examinations for the detection of spirochætes or gonococci were made during the year at the laboratories connected with the clinics and at the Queen's University. Steps were taken for dealing with cases of venereal disease in sailors visiting the port of Belfast.

There were 762 deaths from phthisis registered during the year, equivalent to a rate of 1·8 per 1000. The marked decline in the mortality from this disease in recent years is most satisfactory. In 1901 the death-rate from phthisis was 3·1 per 1000. In 1911 the rate had fallen to 2·1 per 1000, and the rate for 1920 is the lowest in the history of the city. Pneumonia, on the contrary, seems on the increase. In 1905 in an estimated population of 360,000 there were 577 deaths from this disease. In 1920 in an estimated population of 413,000 the deaths from pneumonia numbered 800, as against 712 in 1919. It is instructive to note the relative mortality from phthisis and pneumonia in a long series of years. In 1905 phthisis claimed almost exactly double the number of deaths as compared with pneumonia. The pneumonia figure crept up as that of phthisis declined, and now slightly exceeds the latter.

The least satisfactory item in the report is the relatively high rate of infant mortality, which shows an increase on the previous year. This is the more regrettable as great efforts have been put forth in connexion with the six maternity and child welfare centres. Dr. Bailie complains that expectant mothers do not take sufficient advantage of the information and advice offered at these centres. An infant mortality rate of 132 per 1000 is far too high even for a large industrial and manufacturing centre such as Belfast. It is significant that the rural rate in Ireland, even under poor hygienic condition, is very low, about 60 per 1000, and in some counties the rate is only between 40 and 50 per 1000. The influence of "congenital debility" and "prematurity" is often much exaggerated. The rate in Belfast was 143 per 1000 in 1913, so there has been some slight improvement.

A health exhibition was held in the city in May, 1920, and in connexion with the exhibition a series of lectures were given on housing, tuberculosis, milk, health in schools, oral sepsis, and kindred subjects. Ireland is still without a system of compulsory medical inspection of schools and scholars, a deplorable gap in the machinery of preventive medicine. During 1920 1768 visits to the various schools in Belfast were made, but the powers of the medical officer in this connexion are very limited. On 529 of these visits the number of pupils in attendance was found to exceed the school accommodation. In 11 schools various sanitary improvements were effected. The report is in many respects encouraging.

Ealing.

Ealing, as Dr. T. Orr tells us, is a favoured spot; the borough is almost entirely residential with a few small factories and no real slums, it is well supplied with parks, open spaces, and allotments, and with a lay-out giving plenty of space between the houses; as one would expect, its health statistics make a good showing even in a year of low death-rates. The estimated population in 1920 for birth-rate was 76,290 and for death-rate 76,129. The birth-rate was 17·8, the death-rate 8·8, the infant mortality rate 47, and the death-rate from all forms of tuberculosis 0·74. There has been trouble with the pollution of the Brent by the unsatisfactory effluent from the Wembley sewage works. There is a comprehensive maternity and child welfare scheme which will be rendered more complete by the agreement for the management of the Chiswick and Ealing Hospitals by a joint committee. By this agreement the Ealing Hospital will become the Isolation Hospital and the Chiswick Hospital the Maternity Hospital for the two districts. Eight cases of ophthalmia neonatorum were notified, in two of which permanent damage to the cornea resulted. The council took over a hostel with accommodation for 11 unmarried mothers and their babies in June, 1920. The work of the maternity and child welfare department and the school medical service is well coördinated and carried out in the same building, the only weak spot being that the council have not control of their own midwives. Dr. Orr points out that the two great needs of the school medical work are the provision of a school for mentally defective children and an open-air school for physically defective, anæmic, and poorly nourished children.

SUMMER DIARRHŒA IN LONDON.

The hot, rainless third quarter of the year was fortunately not associated with the devastating attacks of summer diarrhœa that might have been anticipated in light of the experience of the summers of 1899 and 1911. A sign of the topical interest in the extent of summer diarrhœa this year was manifested at the English-speaking Conference on Infant Welfare held in July, when the reading of a statistical paper on the influence of weather conditions on the mortality of infancy elicited an energetic discussion, in the course of which a medical officer of health stated that the number of infantile diarrhœal deaths this year would serve as a measure of the value of the increased supervision of infants instituted during the last decade. Fortunately, judged by this severe standard the work has been abundantly justified. The death-rate from diarrhœal diseases has remained consistently low during the last five years of varying meteorology; this year the records available at present show that, in London at least, although the weekly number of deaths has been considerably above the average of the last five years, nothing like the loss of life which occurred in 1911 has taken place. In 1911, during the weeks ending July 1st–Sept. 23rd, 1997 deaths from diarrhœa and enteritis under 2 years occurred: in 1921 for the same period the number of deaths was 1173.

CATGUT AND SURGICAL NEEDLES: DEMONSTRATION AT THE LONDON HOSPITAL.

ON Oct. 1st a demonstration was given at the London Hospital of the manufacture of ultra-tan catgut. Ordinary commercial catgut cannot with absolute certainty be sterilised by any method which does not also destroy its usefulness as a ligature and suture material, as the hospital found by unfortunate experience during the early part of the war. The London Hospital was, therefore, led to prepare its own surgical catgut under conditions which ensure its sterility. The material they now make and use is the result of several years' experience in manufacture, and gives complete satisfaction to the surgeons of the hospital and others who use it.

The secret of the success of the process is that the gut is rendered sterile throughout its substance at the earliest possible moment in its manufacture, and thereafter mere surface sterilisation is sufficient. The whole process, from the first cutting up of the fresh sheep's gut, is carried out in one building under conditions which resemble those of the operating theatre. The girls engaged in the process "scrub up," and wear caps and overalls; evidently they understand the principles of asepsis. The actual process of preparation consists, briefly, of cutting the gut into lengths, removing the mucous and muscular coats by scraping, and the fat by prolonged soaking in repeated changes of alkali, sterilising in a solution of biniodide of mercury, spinning while wet, and drying. The dried strands, strung separately on a frame which carries a score or more of strands, are then immersed in a hardening

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—Entrance scholarships have been awarded to Mr. H. Mannington, Mr. R. A. Graff, and Mr. F. D. M. Hocking.

GUY'S HOSPITAL PHYSICAL SOCIETY. — The inaugural meeting will be held on Oct. 13th, when Sir Alfred Fripp will give an address. Subsequent meetings will be held on alternate Thursdays throughout the session.

GUY'S HOSPITAL MEDICAL SCHOOL.—The following entrance scholarships have been awarded :—Senior Science Scholarship for University students (War Memorial Scholarship), £75, Bernard G. Scholefield, Christchurch, Oxford. Entrance Scholarships in Arts, £100, Russell C. Brock, Christ's Hospital ; £50, Arnim F. H. Stewart.

FOUR lectures on the Nervous System and the Mind, with its Normal and Abnormal States, will be delivered by Sir Robert Armstrong-Jones at Gresham College, Basinghall-street, London, E.C., on Oct. 11th, 12th, 13th, and 14th, at 6 P.M. *Admission free to men and women.*

PUBLIC HEALTH IN EDINBURGH.—On Sept. 16th the new offices of the Public Health Department in Edinburgh were formally opened by Lord Provost Hutchison, The building in Johnston Terrace was acquired in pre-war times for £3000, being formerly the Church of Scotland Normal Training College, and with internal reconstruction will have cost over £13,000.

KING EDWARD VII. HOSPITAL, CARDIFF.—Sir John Lynn Thomas, having celebrated his sixtieth birthday, is retiring from his position as senior surgeon at this hospital under the age-limit rule. The value of the pioneer work in surgery which he has done at Cardiff, not only at the King Edward VII. Hospital but also in setting on foot the Prince of Wales Hospital, is common knowledge. We are glad to think that his retirement only means that he will now have more time at his disposal for devoting to the many other schemes in which he is interested.

HARROGATE INFIRMARY JUBILEE.—The jubilee of Harrogate Infirmary was celebrated on Sept. 24th. After a reception held by the committee, the Mayor unveiled a brass tablet to commemorate the conversion of the hall into a ward during the war, and the treatment therein of over 600 sick and wounded soldiers. Another tablet was unveiled to commemorate the work of the Harrogate Women's Sewing League, which made nearly two million articles for surgical and medical use. Dr. W. Bain, who presided at the ceremony, said that the total number of in-patients during the 50 years of the hospital's existence had been 16,579, and the total number of out-patients 62,594.

RETIREMENT OF DR. N. H. CHOKSY.—The retirement at the beginning of August of Khan Bahadur Dr. N. H. Choksy from the Arthur Road Hospital, Bombay, serves to recall the great plague outbreaks of the end of the last century in that city, and the distinguished services rendered by him during that period of distress. A pupil of Henry Vandyke Carter at the Grant Medical College, Dr. Choksy took charge in 1892 of the Arthur Road Hospital, which was the only public hospital in Bombay at the beginning of the plague epidemics. The large number of deaths of patients was regarded with suspicion by the ignorant populace of the city, and the hospital premises had to be guarded by troops and police, whilst the doctor and his assistants found armed protection necessary in the streets. The work carried on by Dr. Choksy gained for him the complete and lasting confidence of the authorities and of the white population ; for some years he had the care of a leper asylum, and in 1902 was put in charge of the Maratha Hospital, in addition to his work at Arthur Road. In his 34 years of service he dealt with 25 epidemics of plague, 16 severe epidemics of small-pox, 13 epidemics of relapsing fever, 6 of cholera, and 3 of influenza. The Government conferred upon Dr. Choksy the title of Khan Bahadur at the Diamond Jubilee of Queen Victoria in 1897 ; for his valuable researches into tropical diseases he received numerous foreign honours, including the M.D. (Honoris Causa) of the University of Freiburg, while his work became widely known throughout the world, many foreigners going to Bombay to study plague under his direction. After 1912 much of his spare time was devoted to the work of the King George V. Anti-Tuberculosis League ; during the war nearly 1600 military cases of infectious diseases passed through his hands. Dr. Choksy carries with him into retirement the good wishes of all who know him. Amongst his writings were contributions to THE LANCET during the years 1907, 1911, and 1912, in which he dealt with the treatment of cholera and erysipelas and the propagation of plague.

William Domett Stone, M.D., F.R.C.S., who died in London on Oct. 1st in his eighty-second year, was a great traveller and, in his time, a great sanitary authority. His first contribution to THE LANCET, in 1865, dealt with workhouse reform.

A COURSE IN HELIOTHERAPY.—The success which attended the summer course of lectures and demonstrations given at Leysin during August by Dr. A. Rollier and his assistants has decided Dr. Rollier to repeat the course from Jan. 10th–14th, 1922. An invitation to attend will be sent to any medical man or woman expecting to be in Switzerland, on application to the Secrétariat Médical du Dr. Rollier, Leysin, Switzerland. Applications will be received up to Dec. 15th. Board and lodging (Fr.10 per day) will be reserved for those attending the course.

A MEDICAL OFFICER OF HEALTH'S SALARY.—The Town Council of the Royal Burgh of Stirling invite through the *Stirling Observer* applications for the appointment of medical officer of health, tuberculosis, maternity and child welfare, and V.D. officer, police doctor, and medical attendant at Combination Infectious Diseases Hospital. The combined salary for the work is put by the Council at £500 per annum and no private practice is permitted. The approval of the Scottish Board of Health is said to have been obtained for these terms, which are not likely to recommend themselves to candidates.

GENERAL NURSING COUNCIL FOR ENGLAND AND WALES.—The report of the Registration Committee states that, up to Sept. 30th, 1816 applications for registration have been received, and £1912 3*s.* 11*d.* has been received in fees. Three hundred and sixty-six nurses were recommended to the council for approval for registration on the general part of the register, their qualifications and references conforming in every particular to the rules : 14 for registration on the supplementary part for fever nurses ; and one for registration on the supplementary part for mental nurses. These applicants were approved, and the council agreed to grant a certificate of registration to them. Applicants whose qualifications did not conform to the rules will receive a notification to this effect.

WELSH NATIONAL SCHOOL OF MEDICINE.—The reorganisation needed for carrying out the full curriculum of teaching which is now being embarked upon by the Welsh National School of Medicine is nearing completion. Both the new Board of Medicine and the new Faculty of Medicine have been called into existence. The most important post in this new school is that of dean, and the Faculty recently elected to this post Prof. David Hepburn. Prof. Hepburn has for over 17 years been professor of anatomy at Cardiff, and has acted as Dean of the Medical School, which has been incomplete until now. The experience he has gained in the past will thus be valuable to him in presiding over the full development of the school, to which he has for many years been looking forward. The honour given is great, but greater still is the responsibility, for the work of organising the new National School so as to ensure complete success will be no mean task.

INTERNATIONAL CONGRESS OF EUGENICS.—The second International Congress of Eugenics opened on Sept. 22nd at the American Museum of Natural History, New York. In his presidential address Prof. Henry Fairfield Osborn regretted the growth of an individualism which was threatening the existence of the family, and instanced New England, where large families had been replaced by one-child families ; he foresaw a stage of families with no children, followed by the extinction of the old Republican stock. The American theory that immigrants rapidly became Americanised was worthless ; the vices of commingled races were more surely perpetuated than their virtues. Major Leonard Darwin declared that the results for which eugenists were working might not become apparent for several hundred years, and emphasised the impossibility of attempting to regulate human mating by legislation. He deplored the popular misconception of eugenics which credited that science with the intention to abolish romance and introduce cattle-breeding principles into human domestic affairs. If young people were allowed to follow natural inclination, their mating would usually be wise from the standpoint of eugenics, which did not favour the abolition of love. Many marriages made for wealth or social position did not tend to better the human race. Dr. Charles Davenport, director of the department of genetics, New York, declared that the science of eugenics was sufficiently developed to permit of the determination of a child's parentage through its inherited physical traits. Attention was called to the fact that increasing numbers of persons contemplating marriage were availing themselves of expert advice.

(4) A reduction of the present capitation fee of panel medical practitioners is reported to be imminent. But any such reduction made *before full inquiry* has been held into past results and future requirements, would tend to prejudice future negotiations and alienate the goodwill of those practitioners whose coöperation is essential to the success of the service.

"Representing, as we do, many distinct branches of medical practice and of professions ancillary to medicine, we have considered this matter from widely different angles, ever keeping before us the needs of the community, to which our individual aspirations are willingly subordinated.

(Signed)

BERKELEY MOYNIHAN,
President.

MALCOLM MORRIS,
Vice-President and Rept. of the National Council for Combating Venereal Diseases.

THOMAS HORDER,
Hon. Treasurer.

J. F. GORDON DILL,
Hon. Treasurer.

CHARLES BUTTAR,
Hon. Secretary.

JANE WALKER,
Hon. Secretary.

JOHN ROSE BRADFORD,
London and Counties Med. Protection Society.

H. W. BRUCE,
Infirmary Medical Superintendents Society.

H. J. CARDALE,
Assoc. of Panel Committees.

F. HERNAMAN-JOHNSON,
British Assoc. of Radiology and Physiotherapy.

C. F. RILOT,
British Dental Assoc.

RONALD ROSS,
British Science Guild.

E. H. STANCOMB,
Southampton Medical Parliamentary Committee.

E. H. WORTH,
National Medical Union.

"*Postscript.*—The signatories of this memorandum represent organisations with a combined membership exceeding 16,000. In addition, a number of other medical societies represented in the Federation still have the matter under consideration and a majority of the professional bodies representative of pharmacy, nursing, midwifery, massage, radiography, &c., all of whom are members of the Federation and intimately concerned with the matter, have expressed a wish to subscribe to the memorandum, which, accordingly, has been submitted to their executives. These further names in support of those given will be forwarded at an early date as a supplementary list."

I am, Sir, yours faithfully,
N. HOWARD MUMMERY,
General Secretary.

The Federation of Medical and Allied Societies (Inc.),
12, Stratford-place, W. 1, Oct. 4th, 1921.

THE MARRIAGE BAR.

To the Editor of THE LANCET.

SIR,—In an interesting report in your issue of this week you draw attention to the action of the Borough Council of St. Pancras in requesting one of its medical officers to send in her resignation because she has recently married. Allow me to point out that the Sex Disqualification (Removal) Act, 1919, enacts that: "A person shall not be disqualified by sex or marriage from the exercise of any public function or from being appointed to or holding any civil or judicial office or post, or from entering or assuming or carrying on any civil profession or vocation, or for admission to any incorporated society . . . and a person shall not be exempted by sex or marriage from the liability to serve as a juror."

One or two qualifying provisions follow which have no bearing on the St. Pancras case.

I am, Sir, yours faithfully,
MARY D. STURGE,
President of the Medical Women's Federation.

Oct. 1st, 1921.

THE DANGERS OF THE PUBLIC SWIMMING BATH.

To the Editor of THE LANCET.

SIR,—In the last three years we have had several cases of otitis media in Camberwell Infirmary, following visits to public swimming baths. On August 2nd of the present year, M. S., aged 10, was admitted with a history of three visits to the baths in the previous week, and earache on July 30th, followed by vomiting on the two next days. There were well-marked signs of meningitis when admitted, confirmed by lumbar puncture, a strepto-bacillus being found in the spinal fluid. Death occurred early on August 5th. Post-mortem showed pus in the left middle ear with unruptured drum and an acute lepto-meningitis. The lad was not accustomed to go to the baths and, perhaps, lacked an immunity more frequent visitors might possess.

During a hot summer, like the past, the numbers of bathers are multiplied many times, and the urgency for frequent change of water and its purification is proportionally increased.

I am, Sir, yours faithfully,

Oct. 4th, 1921. G. W. LLOYD.

To the Editor of THE LANCET.

SIR,—Acting upon Dr. F. W. Alexander's suggestion, I have turned to the Report of the Royal Sanitary Institute for information regarding the system employed at the Poplar baths for making and keeping bath-water pure, and I find that the bacterial content of the water may be kept within what may be considered to be the limits of safety for as long a period as a week or ten days at a cost, in 1912, of, apparently, about one shilling and threepence! Dr. J. Graham Forbes in his interesting survey of the methods of disinfecting the water alludes to the plan as giving good results. Surely, then, if this claim can be substantiated the bathing public has the right to ask why this or similar methods are not everywhere in use.

In my former letter I drew attention to the danger of purulent otitis media as a result of bathing in contaminated water. But my indictment does not stop at the ear. Since writing that letter I have seen a case of suppuration of the maxillary antrum in a schoolboy, which the parents ascribed to the same cause, and this case reminds me that some years ago Mr. C. W. M. Hope[1] brought before the Laryngological Section of the Royal Society of Medicine several cases of nasal sinus suppuration which he attributed to infection received during bathing.

While, however, it is but common sense to insist that the water people bathe in should be made as clean as possible, the alternative hypothesis of self-infection must not be lost sight of. And in this connexion Dr. Arnold Renshaw, of Manchester, has pointed out to me that the chilling effect upon the bather of too prolonged a stay in the water must operate powerfully in favouring auto-infection—and extraneous infection also for that matter. Is it too much to ask that a rule should be laid down limiting the period of stay in a public bath? As most of the cases one sees of ear and nose troubles due to this cause occur in children, the rule might be confined to bathers below a certain age.

I am, Sir, yours faithfully,

Wimpole-street, W., Oct. 3rd, 1921. DAN MCKENZIE.

THE NEGLECT OF SURGICAL ANATOMY.

To the Editor of THE LANCET.

SIR,—In his interesting and very important paper in your last issue on a form of injury in the region of the ankle-joint, Sir W. Arbuthnot Lane lets the fault—of improper comprehension and inefficient treatment—rest, "not with the surgeon, but with the teacher." The teacher to whom he refers in this disparagement is, of course, the teacher of surgical anatomy, and the context leaves the impression that his inefficiency is in some way the fault of the teachers of anatomy. This would not appear to be quite just, from the point of view of the anatomists, who might very well argue that it is their function to teach anatomy, while it is that of the surgeon to teach the surgical application of anatomy. So far as the mechanics of the skeleton are concerned, this comes in, naturally, in ordinary teaching in the

Glasgow, Hawkhead Asylum, Cardonald.—Asst. M.O. and Pathologist. £275.

Gloucester County and City Tuberculosis Institution, Standish, near Stonehouse.—Med. Supt. £500.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Res. M.O. £500. H.P. £50.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. Asst. Cas. O. Res. H.P. Each £50.

Leeds General Infirmary.—Anæsth. £25.

Leeds Public Dispensary.—Sen. Res. M.O. £250.

London Fever Hospital, Islington, N.—Hon. Asst. Phys. Hon. Aural Surg.

London Homœopathic Hospital, Great Ormond-street and Queen-square, Bloomsbury, W.C.—Anæsth. £50. Asst. Phys.

Metropolitan Hospital, Kingsland-road, E.—Cas. O. and Res. Anæsth. £120. Sen. H.P. Sen. H.S. Asst. H.P. Asst. H.S. Each £100.

Miller General Hospital for South East London, Greenwich-road, S.E.—Res. Cas. O. £200. Hon. Asst. Ophth. Surg.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Res. H.P.'s and H.S.'s. £50. H.S. to Out-patient Dressing Department. £100.

Oldham County Borough Education Committee.—Asst. Sch. M.O. £500.

Oldham Royal Infirmary.—Sen. H.S. £200.

Perth, Murray Royal Mental Hospital.—Asst. M.O. £350.

Plaistow Fever Hospital.—Second Asst. M.O. £200.

Preston and County of Lancaster Royal Infirmary.—H.S. £200.

Royal Free Hospital, Gray's Inn-road, W.C.—H.S. £50.

Sheffield Royal Infirmary.—H.S. H.S. for Ear, Nose and Throat. Asst. Cas. O. Each £150.

Singapore, Government Medical School.—Professors of Physiology, Anatomy, Medicine, Midwifery and Gynæcology. £1190. Lecturers in Chemistry and Physics, Biology. £840.

Stafford, Staffordshire General Infirmary.—H.P. £200.

Wakefield, Clayton Hospital.—H.S. £225.

Wolverhampton and Staffordshire General Hospital.—H.S. £200.

Births, Marriages, and Deaths.

BIRTHS.

JONES.—On Sept. 24th, at Ashley Gardens, Westminster, the wife of Albert Eastwood Jones, M.D., M.R.C.P., of a son.

LIGHTWOOD.—On Sept. 27th, at a nursing home, Colwyn Bay, the wife of Eric Lightwood, M.B., B.S., of a daughter.

MARRIAGES.

LLOYD—SWINNEY.—On Sept. 27th, at St. Martin-in-the-Fields, London, Edmund Eyre Lloyd, M.R.C.S., L.R.C.P., to Margaret Mary, widow of John Swinney.

DEATHS.

HOOPER.—On Sept. 29th, at the Red Lodge, Aldeburgh, Suffolk, Colonel Sir William Roe Hooper, K.C.S.I., I.M.S. (retired), F.R.C.S., Hon. Surgeon to the King, aged 84 years.

JONES.—On Sept. 29th, at Westcliff Parade, Southend-on-Sea, George Francis Jones, M.R.C.S.Eng., L.S.A. Lond., aged 76 years.

MAYNARD.—On Sept. 20th, of double pneumonia, at Audlem, Cheshire, Lieut.-Colonel F. P. Maynard, F.R.C.S., I.M.S. (retired).

MILLER.—On Oct. 2nd, of syncope, James Duff Miller, M.B., C.M., L.S.A., late of 62, Rotherfield-street, N.1. Sudden death a great shock to all his relatives and friends.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

MEDICAL MISSIONS IN CHINA.[1]

BY HAROLD BALME, F.R.C.S. ENG., D.P.H.

BEFORE I speak of medical mission work as I have seen it in China it is not out of place to recall the medical efforts of the early Church. It was a Christian woman, Fabiola, who founded the first hospital for institutional treatment of the sick in the Western World; Basil, Bishop of Cæsarea, organised the first leper asylum, and the monk Thasalius was responsible for the first asylum for the blind; a Christian merchant, Apollonius, opened a free dispensary; and the Christian Council of Nicæa ordered the foundation of a public institution for the care of the poor in every Christian city.

The practice of mercy has long overflowed the borders of the Christian Church, and in a country such as our own we think of care and responsibility for the sick as hardly touching the activities of the Church; but as was pointed out in last year's Lambeth Conference Report, this care and responsibility has never been removed from the Church.

Pioneers.

In Moslem countries, in China, in Africa, and other places superstition and cruelty are still connected with sickness; preventable suffering is always evident to every missionary doctor and nurse. Few of us in these days have any conception of the difficulties which the pioneers of medical mission work in China had to overcome a hundred years ago. It must be remembered that the reputation of the medical profession in China was then as low as it could possibly be. Abbé Huc, who travelled in China, Tartary, and Thibet, says in one of his writings that the profession of medicine in China was nothing but "a waste pipe, with which to clear off those who are fit for nothing else." This was literally true, with the result that China was swamped with doctors, thousands of whom had no education at all. And what he said has been echoed by every other visitor to China. Anyone was free to practise; anyone was free to call himself a doctor, without any diploma, or college training whatever. The pioneer medical missionaries had to redeem the reputation of medical science in the country before they could make any headway at all. They had to deal with a hostile and suspicious people; and they had to win their way by patience and by the success of their work. They had no equipment, no instruments, no staff; nothing but a strong sense of their double calling, but they went forward and carried on the work with the thought that one day China would produce her own doctors and nurses, and realise her responsibility to her people.

Kenneth Mackenzie, of the London Missionary Society, first started a medical college in China, in 1881. During the Boxer rising of 1900 the results of the work done seemed entirely swept away; but a renewed effort led to the establishment of the inter-denominational medical college in Peking, now financed entirely by the Rockefeller Foundation, although the missionary societies have a voice in its general direction, and in the selection and appointment of the medical staff.

From the small beginning made in Peking branches of the work have spread in other parts of China, and here and there small medical colleges were founded. They were very poorly equipped and manned, but without them even the present condition of medical education would have been impossible. As the Chinese themselves began to recognise the work, it became evident that efficient medical education was absolutely impossible to obtain without a great deal of coöperation, and a willingness to sacrifice local interests to a certain extent. Instead of having a great number of small, understaffed, and inadequately supported colleges, we realised that it is necessary to concentrate on a few, with a staff of well-trained men, and in that way to make a real contribution to the new life of China. It is sometimes urged that in face of the physical needs of the Chinese these institutions should be multiplied; but medical missions do not exist to meet a temporary need; their aim is to sketch an outline for the Chinese to fill in for themselves.

In the Shantung Christian University, with which I am connected, ten missionary societies are represented, and not only has there never been any theological difficulty in the college, but the institution has been able to make an impression on the medical work of China far greater than

---

Medical News.

UNIVERSITY OF DURHAM.—At a special Third Examination for the Degrees of Bachelor of Medicine and Bachelor of Surgery the following candidates were successful:—

Materia Medica, Pharmacology and Pharmacy, Public Health, Medical Jurisprudence, Pathology and Elementary Bacteriology.—Elizabeth M. Anderson, Sydney Basham, Derek C. Bell, William A. Brown, Laurence S. Henry, Bernard R. Isaacs, Louis Minski, Ian M. McLachlan, William A. D. Oliver, Leslie F. Richmond, Henry C. Rollin, William O. Rubidge, and Henry F. Wattsford.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—The President and Fellows of the Royal College of Physicians have decided this year to revive the St. Luke's Day dinner of the College, which has not been held since 1913. The dinner will take place in the College Hall.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The arrangements for conferring honorary fellowships by the Royal College of Surgeons in Ireland on eight American surgeons are now complete, and the delegation of the College appointed to confer the fellowships has left Dublin for the United States. The President is prevented by illness from travelling, and the Vice-President is also unable to leave Ireland at present. The College will be represented, however, by two of its most distinguished ex-Presidents, Sir Robert Woods, M.P., and Sir William Taylor, who are to visit Canada as well as the States in their tour. The compliment paid by the Irish College to American surgery has sprung out of the visit paid to America last year by Sir Berkeley Moynihan and Sir William Taylor on the occasion of the presentation of a mace by British surgeons to the American College of Surgeons.

MEDICAL SOCIETY OF LONDON.—The syllabus of the first half of the 149th session has now been issued. The president for the session is Mr. James Berry, who will deliver his presidential address on Some Medical Experiences in South Eastern Europe (illustrated by lantern slides), at 8.30 P.M., on Monday, Oct. 10th, following an annual general meeting at 8 P.M. On Monday, Oct. 24th, at 8.30 P.M., a discussion on The Modern Treatment of Diabetes will be introduced by Sir Archibald Garrod, to be followed by Sir William Willcox, Dr. O. Leyton, Dr. W. Langdon Brown, Dr. Edmund Spriggs, Dr. E. P. Poulton, Dr. George Graham, and Dr. P. J. Cammidge. Monday, Nov. 14th will be a clinical evening. On Nov. 21st a discussion on the Arseno-Benzol Treatment of Syphilis will be introduced by Lieut.-Colonel L. W. Harrison, followed by Prof. H. Maclean, Dr. J. W. McNee, Dr. R. L. Mackenzie Wallis, Dr. Henry MacCormac, and Mr. C. H. Mills. On Dec. 12th a paper on Hæmorrhagic Bronchitis of Non-Tubercular Origin will be read by Dr. Aldo Castellani, C.M.G., and a demonstration on Dust in Expired Air, given by Dr. J. S. Owens. The Lettsomian Lectures on Amœbic Liver Abscess: its Pathology, Prevention and Cure, will be delivered in February and March, 1922, by Sir Leonard Rogers, F.R.S. The annual oration will be delivered in May, 1922, by Mr. H. J. Waring. Fellows desirous of reading papers should communicate before the middle of December with the Hon. Secretaries, Mr. H. W. Carson and Dr. C. E. Lakin, at the house of the Society, 11, Chandos-street, Cavendish-square, London, W. 1.

ST. MARY'S HOSPITAL MEDICAL SOCIETY.—The sessional programme is as follows, the meetings being held at 8 P.M. in the library of the Medical School:—On Oct. 12th Prof. B. J. Collingwood will speak on Fear; on Oct. 26th Dr. Charles Singer will give a paper on Leonardo Da Vinci as a Man of Science and Anatomist, illustrated by lantern-slides; Mr. C. A. B. Horsford will give a paper on Nov. 16th entitled "Practical Application of Physiological Principles to the Training of the Voice," which will be illustrated by practical demonstrations; on Nov. 30th Prof. Elliot Smith, F.R.S., will speak on Diversions of an Anatomist in Egypt; and on Dec. 14th Dr. C. M. Wilson will give an address entitled "Apologia pro Genere Suo by a Physician." Sir Almroth Wright, F.R.S., will address the Society on Jan. 13th, 1922, on Morals, and on Jan. 27th Dr. Bernard H. Spilsbury will speak on a subject to be announced later. The meeting on Feb. 10th will be devoted to a paper on Sublimation in Psychotherapy, by Dr. J. A. Hadfield. On Feb. 23rd Dr. W. E. Dixon will speak on Tobacco Smoking. On March 10th Prof. A. L. McIlroy will discuss the Value of a Poetical Outlook on Science, and on March 24th Dr. Joseph Barcroft will retail Recent Experiences in the Andes. The President for the session is Prof. F. S. Langmead.

HARVEIAN SOCIETY.—A clinical meeting of this Society will be held at Paddington Green Children's Hospital on Thursday, Oct. 13th, at 4.30 P.M.

ABERNETHIAN SOCIETY.—The sessional address of this Society will be given on Thursday, Oct. 13th, at 8.30 P.M., at St. Bartholomew's Hospital, by Dr. Christopher Addison, on Medical Men and Public Life.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The syllabus of meetings for 1921–22 has just been issued, the president for the year being Dr. E. J. Pritchard. On Oct. 12th the annual dinner will be held at Gatti's Restaurant, Strand. At the first meeting on Nov. 9th, Dr. T. Strickland Goodall will give a demonstration on the Rôle of the Electro-Cardiograph in Practical Medicine. The meetings are held at 9 P.M., at the Bolingbroke Hospital, Bolingbroke-grove, Wandsworth Common, London, S.W. Further information can be obtained from the hon. secretaries, Dr. H. B. A. Pearson, 29, Bolingbroke-grove, Wandsworth Common, S.W. 11, and Dr. C. Dudley Bishop, 60, North Side, Clapham Common, S.W. 4.

SOCIETE D'HYPNOLOGIE ET PSYCHOTHERAPIE.—The twenty-fourth annual meeting of the Society will take place on Tuesday, Oct. 18th, at 4 o'clock, and on Wednesday, the 19th, at 10 o'clock, at 19, rue St. André des Arts, Paris. The programme of the meeting will include an account of psychological work by Dr. Jules Voisin (perpetual president of the Society), and consideration of general questions of progress and present tendencies of psychotherapy, and of "race" in nervous and mental pathology, followed by individual communications. Medical men interested in psychotherapy are cordially invited to attend the meeting and to contribute papers. Communications should be addressed to Dr. Berillon, general secretary, 4, rue de Castellane, Paris 8e.

MIDLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The annual meeting of this Society was held at the Medical Institute, Edmund-street, Birmingham, on Thursday, Oct. 6th, at 4.30 P.M., the Presidential Address on the Position of Obstetrics and Gynæcology under the Scheme of the Welsh Consultative Council of the Ministry of Health was delivered by Dr. Ewan Maclean. The following scientific meetings will be held during the session: At Bristol (Dec. 6th), at Birmingham (Jan. 3rd, 1922), at Derby or Leicester (March 7th), and at Cardiff (April 4th). Papers, short communications, and pathological specimens are invited. Papers and communications, accepted will, at the discretion of the Editorial Committee, be published in the *Journal of Obstetrics and Gynæcology of the British Empire.* The subscription to the Society is 10s. per annum, and the hon. general secretary of the Society is Mr. Beckwith Whitehouse, 52, Newhall-street, Birmingham.

GUILD OF ST. LUKE: ANNUAL SERVICE.—This service, which will this year take the form of a special thanksgiving for peace, will be held on Oct. 18th, at 7 P.M., at St. Paul's Cathedral. The preacher will be the Rev. Father Waggett, and the offerings, after defraying the cost of the service, will be devoted to one of the hospitals in London. Doctors and students are requested to wear academic dress.

KING'S COLLEGE HOSPITAL ANNUAL DINNER.—This dinner was held at the Café Royal, Regent-street, on Sept. 30th. Mr. F. F. Burghard, senior surgeon to the hospital, presided, and proposed the toast of the hospital, to which Viscount Hambleden, chairman of the committee of management of the hospital, replied. Dr. Norman Dalton, senior physician, proposed the toast of the chairman, which was received with musical honours. The attendance numbered a hundred, and included amongst others Lord Gorell, M.C., who had delivered the oration at the opening of the winter session earlier in the afternoon.

LONDON HOSPITAL MEDICAL COLLEGE: *Post-graduate course.*—The "Price" Entrance Scholarship in Anatomy and Physiology, open to students of the Universities of Oxford and Cambridge, has been awarded to Mr. G. L. Thompson of Trinity College, Cambridge. A course of instruction on the Diseases of Children will commence on Wednesday, Oct. 12th, 1921. It will include a course of 10 lectures on General Diseases, to be delivered by Dr. R. Hutchison on Saturdays at 10.15 A.M. in the Anatomical Theatre of the Medical College; a course of eight lectures on Organic and Functional Nervous Diseases and Mental Deficiency, to be given by Dr. Theodore Thompson on Mondays at 9.15 A.M. at the same place; and a course of clinical demonstrations, to be held by Dr. C. H. Miller on Wednesdays, at 10.15 A.M., in the children's out-patient department of the London Hospital. The course will be open to post-graduates and to students of the hospital.

THE VARYING TOXICITY OF NEOARSPHENAMIN.

IN a recent issue of the *Journal of Biological Chemistry*, the chemistry of neoarsphenamin (neosalvarsan) and its relation to toxicity is discussed by G. W. Raiziss and M. Falkov, who have devised methods for the quantitative study of neosalvarsan with especial reference to the sulphur distribution. A low arsenic content may be due to the presence of uncombined sodium formaldehyde sulphoxylate, sulphate or chloride. In good samples the arsenic-nitrogen ratio may equal the theoretical value, and may be taken as an index of purity. The amount of iodine necessary for complete oxidation is in excess of that required for the arsenic group, the excess is attributed to uncombined sodium formaldehyde sulphoxylate, the latter, however, when combined with an amino-group is apparently not oxidised by iodine. The authors conclude that the variation in the substitution in the amino-groups may account for the irregularity of the toxicity and therapeutic effect of this drug.

THE SUPPLY OF ANATOMICAL MATERIAL.

AT a recent meeting of the Romford guardians discussion arose on the evergreen topic of sending bodies to the anatomical schools, the particular case of disposal of the body of an old Indian Mutiny veteran being mentioned. With reference to this last it would surely seem to be the privilege of the War Office to accord to an old veteran the honour of a military funeral, and it would seem equally surely to have been the duty of the guardians to see that the War Office was notified of his death, and not to hurry the corpse off to the "anatomical authorities." But, so far as concerns the general question of anatomical supply, there ought to be no option given to guardians or other vote-catching local celebrities, who know nothing and care less about the vitally important questions concerned. Some may have honest qualms about the matter, though they may be unreasonable, but spurious excitement should be rendered ineffective by leaving the decision in the hands of an educated authority acquainted with the urgent needs of anatomy and yet not devoid of ordinary feelings of humanity.

COLONIAL HEALTH REPORTS.

Barbados.—According to a report for 1919–20 prepared by Mr. Francis Jenkins, Colonial Secretary, the estimated population was 200,368. The birth-rate for the year was 27·5 and the death-rate 30·9 per 1000. No serious epidemic occurred, but typhoid fever was persistent in one district. An offer was made to the Government by the International Health Board (Rockefeller Institute) to initiate a campaign against ankylostomiasis provided that the sanitation of the country districts was improved beforehand by the general adoption of pit latrines for the disposal of excreta. This proviso was not favourably received by the responsible parochial authorities and the Government was in consequence compelled reluctantly to decline the generous offer. Under the head of "Climate" the report says: "Barbados is the healthiest of all the West Indian Islands, and is much patronised by the residents in neighbouring colonies as a health resort. The anopheles mosquito is not found in the Island. The temperature throughout the year varies, as a rule, from 74° to 84° F. The hot and rainy season lasts from the beginning of June to the beginning of November. The island gets the full benefit of the north-east trade-winds, and between November and May the night temperature sometimes falls as low as 64° F. The winter months are regarded as the tourist season. Barbados lies almost out of the track of hurricanes, though it is a matter of history that hurricanes have swept over the island at intervals, notably in 1780, 1831, and 1898, and have done great damage."

Leeward Islands.—The estimated population on Dec. 31st, 1919, was in Antigua 31,063; St. Kitts, 27,193; Nevis, 14,390; Anguilla, 4988; Dominica, 40,315; and Montserrat, 11,168. The birth-rate for the year 1919–20 was 34·1 per 1000 in Antigua, 30·6 in St. Kitts, 30·0 in Nevis, 36·5 in Anguilla, 37·9 in Dominica, and 34·3 in Montserrat, whilst the death-rate, taking the provinces in the same order, was 26·9 per 1000, 25·2, 20·4, 26·4, and 17·5. The general health of the Colony was satisfactory, but no great advance in health and sanitary conditions will be made until the people as a whole are brought to realise the importance of cleanliness in elementary habits and of ventilation and a well-regulated diet, especially for infants. During the year 3688 patients were admitted into the hospitals, and of these 335 died. The average number of inmates in the Central Lunatic Asylum at Skerretts, Antigua, was 158. There are two leper asylums, one at Rat Island, Antigua, and the other at Fort Charles, St. Kitts. The average daily number of inmates in the former was 30 and in the latter 73.

Bermuda.—In the report for 1920 it is stated that the civil population is estimated at 21,987—7500 white and 14,478 coloured. The birth-rate was 20·1 per 1000 among the whites and 29·35 among the coloured population, the death-rate being 12·24 for the former and 18·57 for the latter. In regard to public health the general conditions are very good, and with a little improvement in certain directions could be made almost beyond fault. There are no tropical diseases other than an occasional mild type of fever diagnosed as dengue. This, however, is neither frequent nor widespread. Malaria is unknown. A certain amount of tuberculosis (34 deaths in 1920) is found, which is often contracted by the coloured inhabitants who leave the islands to work in northern climates. Having contracted it they return to the colony, where it develops and sometimes is conveyed to other members of the family. During the summer months there is a good deal of enteritis among children, which can, however, be avoided by care in keeping food, milk, &c., free from flies and perfectly fresh. A mild type of typhoid also occurs spasmodically in the summer months, but is not common and seldom spreads. Each house has its own rain-water cisterns, the only water-supply, so that infection is rarely spread through infection of water. With ordinary care and cleanliness these infections can be and are avoided by the vast majority. Taken all round, the climate and conditions make Bermuda one of the healthiest spots in the Empire. The very agreeable character of the climate during the greater part of the year no doubt is of great value in the preservation of health. There are no extremes of heat or cold, and even during the summer months of July, August, and September the atmosphere, though at times enervating and excessively humid, is not really trying to those who get sufficient outdoor exercise. The social condition of the coloured population is greatly superior to the average in most colonies of similar character, as will be readily apparent to any observer who notes their neat, substantial dwellings and general orderly behaviour. There are very few paupers. About 12,000 tourists are estimated to have visited the colony during 1920. The "season" runs from November to the end of April or early May. The outlook for the tourist industry is excellent. The steamers provided by the New York–Bermuda service are fast and admirably equipped, and local attractions are being developed.

THE USES OF DOG.

THOSE who are interested in the promotion of Bills to prevent experimentation with dogs might feel tempted to extend their measures to include an interdiction of the therapeutic uses of the same animal, were they to study Dr. J. Roshem's witty essay in a recent number of the *Paris Médical*.[1] He has discovered in the pages of a French periodical, published on August 27th, 1759, a recipe for the preparation of *bouillie* to be applied to gouty joints, the virtue of which only appears when a puppy is introduced to the sick room. The smell of the preparation attracts his attention. He is encouraged to taste it and so lured to his misfortune, for the hapless dog speedily swallows not only the dish prepared for him, but if we must believe the journal, much more beside: "The friction of his tongue upon the patient's skin opens the pores, favours the introduction of the saliva, as well as perspiration, and the consequent escape of that part of the gout which lies nearest the epidermis and so on successively until all the morbid material is destroyed." Destroyed, that is to say, from the patient's point of view, for the pseudo-scientific explanation is merely the cloak of a superstition which is found at all times (even to-day) and amongst all peoples and which teaches that disease may be transmitted from the afflicted body to another which is young and vigorous.

The dog is also valuable after death. It is interesting to note that Dr. Lémery's only comment on the puppy ointment which appears in his pharmacopœia[2] is that the proportion of puppy derivatives—fat, spinal cord, and oil—is too low. There are to be found in the same work recipes for puppy oil and puppy liniment. The latter, a mixture of dog and mole, is a sovereign remedy for sciatica and rheumatism. It would be interesting to trace the origin of this form of treatment.

A. D.—A new edition of W. B. Cannon's "Bodily Changes in Pain, Hunger, Fear and Rage" appeared in 1920, and was reviewed in THE LANCET, 1920, ii., 75.

Corrigendum.—In the report of the Industrial Welfare Conference at Oxford appearing last week, the name of the representative of the Trade Union Congress should read Mr. F. Bramley.

THE Medical Branch of the Board of Education has been transferred from Bridgewater House, Cleveland-square, London, S.W. 1, to Nos. 5 and 6, Clement's Inn, Strand, W.C. 2. (Telegraphic Address, "Meducation Estrand, London.")

[2] Pharmacopée Universelle contenant toutes les Compositions de Pharmacie. Published by De Saint et Saillant. Fifth edition, 1763.

NORTH-EASTERN ASSOCIATION FOR THE CARE OF THE FEEBLE-MINDED.—The annual meeting of the association was held at Monkton Hall, Jarrow, on Sept. 24th, Sir Thomas Oliver being in the chair. The financial statement for the year ended on July 30th was described as very satisfactory; a deficit of nearly £300 had been turned into a surplus of £165. The institute had its full complement of boys, but a number of Newcastle Union cases would shortly be transferred to Prudhoe Colony. In moving the adoption of the report presented by Mr. J. Stewart, Sir Thomas Oliver said that at the present time a feeble-minded boy was rarely seen, for most of them had been gathered into homes where they were trained and to some extent educated. It was a mistake, and in a sense a crime, to allow feeble-minded girls to have liberty. The physical and mental activities of defective children could be largely restored if the children were placed under proper treatment at an early age. Although the boys were received at Monkton Hall too late in their lives, many of them had been sufficiently restored to leave the home and earn something for themselves.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Oct. 10th.

WAR SECTION: at 5.30 P.M.
Presidential Address:
Sir John Goodwin, Director-General, A.M.S.: The Aftermath of War, with Reference to the Medical Service of the Army.

Thursday, Oct. 13th.

SECTION OF NEUROLOGY: at 8.30 P.M.
Presidential Address:
Mr. Percy Sargent, C.M.G., D.S.O., F.R.C.S.: Some Observations on Epilepsy.

Friday, Oct. 14th.

CLINICAL SECTION: at 5.30 P.M. (*Cases at 5 P.M.*)
Exhibition of Cases.

SECTION OF OPHTHALMOLOGY: at 8.30 P.M.
Demonstration (at 8 P.M.):
Miss Ida C. Mann: A Series of Models illustrating the Development of the Human Eye.
Papers:
Mr. J. Herbert Parsons: The Fourth Cranial Nerve.
Mr. Ernest Clarke: Milestones in Refraction Work.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Oct. 10th.—8 P.M., Annual General Meeting. 8.30 P.M., Presidential Address:—Mr. J. Berry: Some Medical Experiences in South-Eastern Europe (illustrated by lantern slides).

SOUTH-WEST LONDON MEDICAL SOCIETY.
WEDNESDAY, Oct. 12th.—Annual Dinner at Gatti's Restaurant.

HARVEIAN SOCIETY, Paddington Green Children's Hosp., W.
THURSDAY, Oct. 13th.—4.30 P.M., Clinical Meeting.

NORTH OF ENGLAND OPHTHALMOLOGICAL SOCIETY, at the Manchester Royal Infirmary.
FRIDAY, Oct. 14th.—2.30 P.M., Exhibition of (1) Anatomical Collection Illustrating the Eye and its Adnexa, prepared by Prof. Stopford; (2) Macroscopical and Microscopical Preparations of Pathological Conditions of the Eye by the Hon. Staff of the Royal Eye Hospital; (3) Collection of Drawings presented to the Royal Eye Hospital by Dr. Hill Griffith. Clinical Cases:—Mr. A. E. Burroughs: Conical Cornea successfully Treated with the Electric Cautery. Mr. J. Gray Clegg: Chronic Glaucoma in a Young Subject; Uveitis with Absolute Central Scotoma; Melanosis of the Eye, Temple, and Palate; Correctopia with Extreme Miosis. Mr. H. H. McNabb: Recurrent Neuro-fibroma of the Optic Nerve. Mr. W. Stirling: Recurrent Orbital Growth. 5 P.M., Election of New Members. Clinical Discussion. Papers:—Mr. Clegg: Abnormalities of the Visual Field—an Experience of 22 Years of Private Practice. A Preliminary Note on Uveitis with Absolute Central Scotoma. 7 P.M., Dinner at the Brazennose Club.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Oct. 10th.—10 A.M., Dr. G. Stewart: Neurological Department. 12.15 P.M., Dr. Burnford: Pathological Demonstration. 2 P.M., Dr. Simson: Diseases of Women. Dr. S. Pinchin: Medical Out-patients. 2.30 P.M., Mr. Addison: Demonstration of Cases (Surgical Wards). 5 P.M., *Lecture*:—*Dr. A. Saunders*: Digestive Troubles of Infancy.
TUESDAY.—10 A.M., Mr. Steadman: Dental Department. 11 A.M., Dr. McDougal: Electrical Department. 2 P.M., Dr. Burrell: Medical Out-patients. Dr. Pernet: Skin Department. 2.30 P.M., Dr. Pritchard: Demonstration of Cases (Medical Wards). 5 P.M., Lecture:—Dr. Pernet: Ringworm.
WEDNESDAY.—11 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Dr. Owen: Medical Out-patients. Mr. Gibb: Eye Department. Mr. D. Armour: Visit to Surgical Wards. 5 P.M., Lecture I.:—Mr. T. Gray: Surgery of the Mesentery.
THURSDAY.—11 A.M., Dr. Simson: Gynæcological Demonstration. 2 P.M., Mr. MacDonald: Surgical Out-patients. Mr. D. Armour: Operations. 2.30 P.M., Dr. Saunders: Demonstration of Cases (Medical Wards). 5 P.M., Lecture I.:—Mr. Simmonds: Surgical Emergencies.
FRIDAY.—10 A.M., Mr. D. Buxton: Dental Department. 2 P.M., Dr. Burrell: Medical Out-patients. Mr. Sinclair: Surgical Out-patients. 2.30 P.M., Mr. Addison: Operations. 5 P.M., Lecture:—Dr. Burnford: Infective Endocarditis.
SATURDAY.—10 A.M., Dr. A. Saunders: Medical Diseases of Children. Dr. Burnford: Visit to Medical Wards.
Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, Marylebone, W.
MONDAY, Oct. 10th.—11 A.M., Dr. Goodall: Out-patients, 2 P.M., In-patients. 5.30 P.M., Lecture:—Dr. J. Parkinson: Aortic Disease.
TUESDAY.—10 A.M., Dr. Parsons-Smith: Out-patients. 11 A.M., Dr. Price: In-patients. 2 P.M., Sir S. Russell-Wells: Out-patients.
WEDNESDAY.—10 A.M., Dr. Parkinson: Out-patients. 2 P.M., Dr. Moon: In-patients.
THURSDAY.—2 P.M., Dr. Price: Out-patients. Dr. Moon: In-patients. 6.30 P.M., Dr. Hamill: Out-patients.
FRIDAY.—10 A.M., Dr. Parsons-Smith: Out-patients. 2 P.M., Dr. Parkinson: Out-patients. 3 P.M., Dr. Parkinson: In-patients. 4 P.M., Dr. Hamill: In-patients.
SATURDAY.—10.30 A.M., Dr. Hamill: In-patients.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Oct. 13th.—4 P.M., Lecture:—Mr. O. L. Addison: Acute Infections of Bone.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.
THURSDAY, Oct. 13th.—6 P.M., *Chesterfield Lecture*:—Dr. W. K. Sibley: General Principles of Treatment.

maximum criminality is the period 16–21, the period of adolescence. The proportion of criminals to population of the same age is at its highest during that period, and falls steadily in each successive age-group.

TABLE I.—*Relation of Criminality to Age.*

Proportions at different age-periods—per 100,000 of population—of persons convicted of indictable offences in England and Wales in the years 1893 and 1905.

Age.	1893.	1905.	Age.	1893.	1905.
Under 12 ...	24	23	30 to 40 ...	204	210
12 to 16 ...	261	218	40 to 50 ...	143	158
16 to 21 ...	*321*	*275*	50 to 60 ...	92	91
21 to 30 ...	245	247	Above 60 ...	56	53

That is, of course, what we should expect to find if crime were due, in any important measure, to weakness of inhibitory control; in the years of adolescence, when the power of restraining and regulating impulse is still feeble and immature, the criminal tendency should be greatest; with the advance into manhood and the gradual establishment of self-control and the capacity of subjecting instinct to the governance of legal and moral standards, the frequency of crime should decrease. And it may be added that we should expect to find just the reverse condition if crime were, as it is sometimes asserted to be, the result of a specific anti-social disposition, the manifestation of a specific criminal diathesis. On that theory criminality, instead of decreasing, should tend to increase with age, by the addition from each successive age-group of new recruits to the army of constitutional and instinctive law-breakers.

Age, then, is a condition which appears to affect criminal tendency mainly through its relation to the power of self-control; it modifies the strength of impulses, too, no doubt, but its more important and effective action is clearly on the degree of capacity to restrain and govern impulsive activity.

Seasonal Fluctuations of Sexual Offences.

In the seasonal fluctuations of sexual offences, to which I have next to direct your attention, we have, on the other hand, an instance of the modification of criminal tendency through constitutional influences affecting mainly the strength of impulse. The increase of sexual activity in the spring and early summer is, of course, a well-recognised fact throughout the animal world, and appears clearly in Tables II. and III. The figures in the right-hand column show that the number of conceptions is higher in the months of May and June than in any other month of the year; and that rape and indecent assaults occur most frequently in June. It is reasonable to infer from the close correspondence of the statistical movement of these two sets of phenomena that the rise in the frequency of sexual offences depends on the same cause as the increase in the number of conceptions, and that this common underlying cause is a heightening of sexual activity, an increase in the strength of the sexual impulse.

ABNORMALITY OF IMPULSE AND FAILURE OF INHIBITION.

These two points are of immediate interest and significance in relation to the matters which we have to discuss in this lecture; for they illustrate the operation of two factors which play a large part in the conduct disorders of the mentally defective. The inadequate capacity of control which is a temporary condition in adolescence, and is presumably the source of the special criminal proclivity characteristic of that time of life, is, in greater or less degree, a regular and permanent feature in many cases of mental deficiency. And though the impulses of the feeble-minded do not generally exhibit any constant difference, qualitative or quantitative, marking them off from the impulses of normally developed persons, it is not uncommon to observe instances where mental deficiency is associated with an excess or perversion of instinctive activities, leading to criminal acts which seem then to be related more to abnormality of impulse than to failure of inhibition.

Bearing these facts in mind, we shall naturally conclude that mental defect is likely to involve some degree of predisposition to crime, or at all events to some sorts of crime. And this conclusion is confirmed by the fact that the proportion of weak-minded persons is considerably higher amongst convicted criminals than it is in the general population; in this country, for example, it has been estimated that from 10 to 20 per cent. of the inmates of prisons are mentally defective, while in the general population the proportion is supposed to be 0·5 per cent. These estimates, of course, are arrived at by rather rough-and-ready methods, and we need not rate their accuracy very highly; moreover, the prison population is not representative of criminals as a class, but only of convicted criminals, and mental deficiency, if it predisposes to crime, predisposes even more certainly to detection. Still, when full allowance has been made for the conditions qualifying their value, we may take these figures as showing that the proportion of mental defectives is in fact considerably larger amongst people who break the laws than amongst people who obey the laws. *This conclusion does not, however,* tell us much until we carry our analysis a little further and ascertain with what forms of law-breaking mental deficiency is specially associated.

FORMS OF CRIMINALITY ASSOCIATED WITH MENTAL DEFICIENCY.

Table IV., taken from Dr. Charles Goring's work on the English Convict, gives some information on this point. It shows the percentage of mental defectives in a population of 948 convicts, classified according to the nature of their offences. As you will observe, the incidence of mental deficiency varies enormously from one group to another. Amongst criminals convicted of the more skilled offences, such as embezzlement and forgery, offences which for the most part imply intelligence and education—there are no defectives. At the other end of the scale are the

TABLE IV.—*Proportion of Mental Defectives amongst 948 Convicts Classified According to the Nature of their Crimes.*

Stealing	11·2		

the sum of its individual units, standing for economy of work and administration, and proving to the Chinese that the profession of different forms of Christianity does not hinder coöperation in medical matters.

Hospital Work and Nursing.

The students come from every part of China, mostly out of our missionary colleges—not because Government students are not willingly accepted, but because, in the present condition of State education, few Government students have been able to attain matriculation standard. That condition of things will soon pass; one progressive governor is already having our examination held in his own capital every year, and helping to prepare students for it; those who pass are coming to our Christian University, in order that they may eventually return and help to staff a medical college which he is building in his own capital—all this in spite of the fact that ours is a purely Christian institution. Our students come to us for seven years, and owing to this concentration which I have just mentioned, we now have a staff of over 20 whole-time teachers. We never regret it when we see our students going into private practice, or into the public service; but naturally we like best to see students voluntarily choose the service of the mission hospital, instead of the better-paid service of the Government institution. Of our 53 last year's graduates, 46 are in mission hospitals. Our total number of graduates up to the present time is 115; of these 110 have served for periods in mission hospitals, and over 80 are in that service to-day.

The development of the medical profession in China has been followed by that of the nursing profession. Ten years ago, except at the Treaty ports, it was impossible to get any educated girl to touch the work of nursing; to-day there are 52 training schools for nurses, all of them giving standardised training, in most cases a four years' course. All these training schools are connected with medical missions. Education and scholarship have always been considered highly in China, and to-day the Chinese are losing their superstitions and changing their ideals; it is in the power of the new nursing service to exercise a great influence in the country at the present time. It is a great privilege to take some part in the education of the men and women who will be the future doctors and nurses of China; we of the medical missions feel that in these days we have a splendid opportunity offered us at a time when the Chinese people are perhaps more impressionable than ever before in their history.

LOOSE NECKWEAR IN EPILEPSY.

To the Editor of THE LANCET.

SIR,—In view of the ridicule excited by my first pamphlet on "*Cerebral Congestion and Tight Neckwear*" published some years ago, ridicule especially directed to my observations concerning tight neckwear and epilepsy, I now relate the following case:—

On May 1st, 1921, I saw a woman, aged nearly 50, who had been subject to epilepsy since she was eight years old. She had sometimes had as many as five or six fits a day, and had rarely been many days free from them. She had been under many different doctors at different institutions. The only treatment I suggested was perfectly loose neckwear with no neck ribbon or neck chain. She at once took my advice, and up to Sept. 18th, nearly five months afterwards, she had only had about five fits—i.e., rather less than she had often had previously in a single day.

A few years ago I had treated in a similar way a somewhat similar case, a woman of 32 or 33, who had been epileptic for some 25 years. The seizures gradually died away and for some years she has been free from them and is in very much better general health.

I may add that I have retired from practice for many years.—*I am, Sir, yours faithfully,*

WALTER G. WALFORD, M.D.

Finchley-road, London, Sept. 19th, 1921.

"THE GATEWAY TO HEALTH."

IN May, 1920, a conference on the prevention of dental caries, held at Manchester under the auspices of the Food Education Society, was widely attended by medical men, dentists, and public officials, who discussed on basic principles the relations between good teeth and national health. The proceedings of this conference have now been edited by Mr. Chas. E. Hecht, M.A., and published in convenient book form with the above title at the St. Catherine Press (pp. 431, price 12*s.* 6*d.*). Prof. J. G. Adami's inaugural address to the conference may be studied with advantage now, when the new Dentists Act is on the point of coming into force. Mr. Hecht has incorporated a large number of striking facts and statements which will be useful to public speakers. A first-rate index renders reference easy.

AIR TRAVEL IN FRANCE.

COMMERCIAL aviation has only existed in France for two years, but during this time numerous air services have been established under the supervision of Mr. Laurent, Under-Secretary of State for Aeronautics, assisted by Colonel Saconney, Director of Air Services. The State grants bounties to the companies based on the number of kilometres traversed, and last June French air companies carried 1553 passengers, against 100 at most carried by British companies.

The *Economic Review* gives from French sources a schedule of the traffic carried in 1919 and 1920:—

	1919.	1920.
Paying passengers	729	5,561
Goods (kg.)	14,080	121,195
Mails (kg.)	466	5,967
Completed journeys ..	1,173	4,052
Kilometres traversed ..	354,115	1,503,071

The longest journey at present undertaken is that from Toulouse to Casablanca, Morocco, performed four times weekly in each direction.

Toulouse	dep.	10.30 A.M.	
Barcelona	arr. dep.	1.0 P.M. 2.30 P.M.	lunch.
Alicante	arr. dep.	6.0 P.M. 6.0 A.M.	spend the night.
Malaga	arr. dep.	11.30 A.M. 1.0 P.M.	lunch.
Rabat	arr.	4.0 P.M.	
Casablanca	arr.	5.30 P.M.	

Other foreign services are: Paris (le Bourget) to London (Croydon), four times daily in each direction in 2½ hours (two English companies perform the journey twice daily in each direction); Paris–Brussels (2 hours)–Amsterdam in 4 hours 45 minutes; Paris–Strasbourg–Prague (7 hours); Warsaw, daily (except Sunday) in 12½ hours, carrying the mails; Bayonne–Bilbao–Santander daily in 2½ hours. Services within France include: Bordeaux–Toulouse–Montpellier, in 3½ hours; Montpellier–Nimes–Avignon–Nice, twice weekly in each direction in 2½ hours.

THE PRESS CONGRESS AT HONOLULU.

FROM Oct. 11th to the 25th a Press Congress of the World will take place at Honolulu, on the island of Oahu, an eminently suitable theatre for the expression of international interest and goodwill. Situate in mid-Pacific, the Hawaiian (Sandwich) Islands are already occupied by a mixed population, the different elements of which have learnt to live together in amity; the climate is one of the best in the world, and the city of Honolulu, "the Paradise of the Pacific," will prove an ideal centre for the Congress. The business sessions will be held in the throne room of the royal palace of the Hawaiian monarchs. The programme of entertainments has been planned to display every phase of the life of the islands. Among the excursions of interest will be a visit to the great volcano of Kilauea on the island of Hawaii, and a distant glimpse will be obtained of the leper settlement at Kalaupapa on the northern coast of the island of Molokai. One day of the Congress will be set aside for the holding of a Pan-Pacific Press Conference under the auspices of the Pan-Pacific Union for frank discussion of problems of the Pacific.

PHYSIOLOGY AND HYGIENE FOR CHILDREN.

THE Modern Physiology, Hygiene and Health School Series, which is under the general editorship of Dr. William F. Russell, is designed to induce children to think about health. In two volumes[1] of this series, entitled "The Most Wonderful House in the World" and "The Play House," by Mary S. Haviland, Research Secretary of the National Child Welfare Association, the author has, in her own words, tried "not to convey the maximum number of facts, but to arouse the maximum degree of interest. Facts may be quickly forgotten, but interest, once fully aroused, never quite dies." "The Most Wonderful House in the World" is a primer dealing with the mechanism and hygiene of the body, and is suited for the use of quite young children. No attempt is made to cover the whole field of physiology, but such questions as water, food, indigestion, sleep, and clothes are discussed in a way calculated to appeal to the mind of a child. The volume entitled "The Play House," dealing with questions of home hygiene, is slightly more advanced. Both books are pleasant in design and execution and can scarcely fail to interest children in the workings of the human machine and in the laws of hygiene and health, though we opine that some of the more astute may be secretly scornful of the artificial family whose recited adventures veil so much useful information.

unprofitable perversity. It is quite true that in most instances of moral imbecility some such indications may be found, and that careful and methodical examination will show evidences of intellectual inferiority as well as of ethical debility; but there are many cases where this is not so, and where the proof of mental defect can only be gathered from the whole record and circumstances of the individual's anti-social conduct—from the lack of foresight and judgment which he reveals in his criminal acts, from his failure to appreciate their certain and disagreeable reaction on his own comfort and liberty, despite repeated experience of punishment.

If by "permanent mental defect" the definition means a defect of intelligence that can be made out without reference to the imbecile's aberrations of conduct, then there does not seem to be any good reason for taking him out of the category of feeble-minded persons, and the definition is superfluous. If, on the other hand, the character and incorrigibility of the vicious and criminal conduct can of themselves provide sufficient evidence of intellectual weakness, the separate reference to "mental defect" is misleading and likely to be a source of practical difficulty, and this all the more through the addition of the adjective "permanent" to qualify a condition which, for ought we know in any given case, may be, and, in point of fact, very often is, temporary.

CLINICAL CONSIDERATION OF MORAL IMBECILITY.

It will be more profitable for us, therefore, to put this definition quite out of our minds and, leaving aside all theoretical views, to go back to the consideration of the moral imbecile from the purely clinical standpoint.

What is usually found, then, is that the criminal conduct of these imbeciles is distinguished by the precocity of its appearance, by the variety of its direction, and by its occasionally gratuitous character. The ordinary criminal—I am speaking now of habitual offenders—may start pretty early on his anti-social career, but he does not commonly begin in early childhood, and, as a rule, he is more or less of a specialist in his criminal activities, which are almost always directed to acquisitive ends. The moral imbecile, on the contrary, is generally an incorrigible thief and liar from the time that his physical and mental development will allow of thieving and lying; he is often fiendishly cruel to younger children and to animals; he is precociously vicious in sexual matters; and his subsequent criminal record may include quite a number of different types of offence.

Of course, as the moral sense "is not a simple activity, but the sum of a set of tendencies" (Ribot), the character of the emotional deficiency may vary very widely in different cases, according as one or other of the constituent elements is lacking, or is imperfectly developed; and since, moreover, the form that the impulses eventually assume, and the ideas that become connected with them, are largely influenced by training and circumstance, it follows that the conduct in which moral imbecility expresses itself may exhibit much apparent diversity. In all cases, however, there is the common trait of insensibility in respect of the particular form of moral feeling involved, with an entire incapacity for experiencing shame or remorse. Individuals of this sort may be taught moral ideas, and in fact they are very ready with the names of the nobler emotions when it is to their interest to conceal their defect, but they are incapable of the feelings and impulses related to these ideas; their morality, as Schüle puts it, is purely theoretical.

EPILEPSY: HEAD INJURIES: RETARDED DEVELOPMENT.

Unfortunately, we still lack satisfactory means of detecting and measuring this moral insensibility; ethical discrimination tests, and the theoretical solution of difficult moral situations, are tests of intelligence, not of feeling, and moral imbeciles often respond most brilliantly to them. There are two points of special interest to be observed in connexion with this form of mental deficiency—first, its affinity to epilepsy, as shown by its frequent occurrence in the offspring of epileptic stock, and by the occasional supervention of epileptic fits later in the subject's life; and, second, its apparent relation in some instances to head injuries in childhood. Well-marked cases of true moral imbecility—that is to say, of moral insensibility and precocious vice, with relatively little evidence of intellectual defect—are by no means common amongst criminals; and their rarity is a further argument against the assumption of a specific criminal diathesis as the fundamental factor in anti-social conduct.

Rather more frequent in criminal practice are instances in which a condition somewhat resembling moral imbecility exists during childhood and adolescence, or perhaps about puberty, but is due merely to retarded development and not to permanent deficiency. Homicidal crimes, often with an obvious element of sadist perversion, are occasionally committed by youths in this stage of emotional and moral immaturity; just as in girls it is not uncommon to meet with arson, and, even, though more rarely, with murder, as criminal manifestations about the time of the establishment of the menstrual function.

THE PATHOLOGICAL SWINDLER.

Before leaving this subject, some reference may be made to one particular group of mentally abnormal criminals, who, though their ethical defect is of a less generalised character, may be counted in the category of moral imbeciles—namely, the pathological swindlers. These individuals differ from the ordinary sane impostor in the degree in which their swindling propensities dominate their character and colour all their activities—they are exercising a talent rather than practising a trade—and even under the hampering conditions of prison or asylum life, they will continue to lie and cheat, not merely for trivial advantages but quite gratuitously, when there is no prospect of gain and a practical certainty of detection with the attendant risk of loss of privileges. A similar mental abnormality may be found in certain women criminals addicted to blackmailing and slander.

In pathological swindlers the level of intelligence is generally pretty high, so that, for evidence of their mental debility, we have to rely mainly on the precocity and incorrigibility of their perverted conduct, and on their persistent display of the same tendencies in the absence of intelligible motive. In some instances, also, it is possible to bring out the constitutional character of their unveracity by testing their ability to give accurate evidence. Some of these subjects, for example, when tried with the ordinary method in which the details of a picture or a statement are to be recounted from memory, will distort and amplify the original facts with a most remarkable wealth of fantasy, and with every appearance of conviction as to the truth of their testimony. This test, however, is successful only in a minority of cases.

CRIMINAL RESPONSIBILITY OF MENTAL DEFECTIVES.

To conclude this lecture it remains to refer shortly to the question of the criminal responsibility of mental defectives. Prior to the passing of the Mental Deficiency Act of 1913, a mentally defective person charged with a criminal offence could not be dealt with otherwise than under the ordinary practice of the courts in respect to the plea of insanity—that is to say, if the offender's defect of mind were such as to render him insane so as not to be responsible, according to law, at the time he committed the act imputed to him, the jury could find him "Guilty, but insane," and he would then be detained as a criminal lunatic. If his mental deficiency fell short of that degree, he was held liable to ordinary punishment. And it was in fact laid down explicitly in several judicial decisions that mere mental deficiency does not entitle a jury to return the special verdict under the Trial of Lunatics Act.

The Mental Deficiency Act established a new mode of procedure; under Section 8 of that Act it is pro-

A Lecture

ON

CRIME AND MENTAL DEFICIENCY

Delivered at the University of London, as Part of the Course of Post Graduate Lectures on Mental Deficiency,

BY W. C. SULLIVAN, M.D. R.U.I., B.CH., B.A.O.,
MEDICAL SUPERINTENDENT, BROADMOOR CRIMINAL LUNATIC ASYLUM

AN inquiry as to how and to what extent arrest or perversion of mental development may be concerned in bringing about anti-social conduct must begin with a critical examination of the ideas attached to the terms crime and criminal.

This examination is particularly important, because in discussing the connexion of criminal conduct with a biological condition such as mental deficiency there is a natural tendency to think and speak of crime and criminals as if the conceptions represented by these words were also of the biological order—as if crime were a simple and definite phenomenon with a distinctive organic basis, and as if criminals formed a homogeneous group with specific biological characters. Some such assumption is, in fact, very often made more or less consciously by people who theorise about the criminal temperament, the criminal diathesis, the heredity of crime, and so forth.

SOCIOLOGICAL CONNOTATION OF CRIME

In reality, however, the view of crime which these theories imply is quite false and misleading. Crime and criminal are terms that connote sociological and not biological conceptions. A crime is an act or omission forbidden by the law under pain of punishment. Crime, that is to say, is created by the law. Laws are the formal expression of the will of the community, and acts or omissions that conflict with that will, as formulated in the penal code, are criminal. The criteria of criminal conduct are thus furnished by the law, and by the law alone; the only common character which belongs to all the aberrations of social conduct that we call criminal is their illegality. Now it is obvious that the acts which are brought into a single category by reference to such a standard as this must be—as they notoriously are—very widely different in their nature and origin, and in the mode and degree of their dependence on the numerous and complex conditions which may determine or influence social conduct. The imbecile who fires a stack for the pleasure of seeing a blaze, the underpaid clerk who embezzles his employer's money under exceptional economic stress, the man who kills his wife's seducer, the skilled burglar, the expert coiner, the area sneak, the epileptic homicide—all these are criminals, but what characters have they in common to constitute a specific type, a biological group? And if we try to evade this difficulty by subdividing criminality into its several kinds according to what we may suppose to be the predominant impulse characterising each kind, we are still very far from anything approaching a biological classification—"thieves" or "homicides" are not biological categories any more than are "criminals." For the aptitudes, and in most cases the fundamental impulses concerned in criminal acts, or in any particular class of such acts, have nothing specifically criminal about them; they are essentially the same impulses and the same aptitudes that come into play in non-criminal conduct; the acquisitive impulse that informs the activities of the burglar does not differ in kind from that which directs the energy of the law-abiding artisan, and the aptitudes which burglar and artisan display in their respective callings may be practically identical—their essential character is not affected by the fact that the resultant conduct is illegal in one case and legal in the other.

NON-EXISTENCE OF SPECIFICALLY CRIMINAL APTITUDES

Conduct, then, may be criminal, but there are no criminal aptitudes, and it is only rarely, and in a more or less figurative sense, that we can speak of criminal impulses. Now while it may be possible to bring impulses and aptitudes into direct relation with biological conditions, it is clear that we cannot establish such an immediate relationship in the case of conduct; conduct, whether criminal or non-criminal, depends also, of course, on biological conditions, but it is not a direct and immediate result of such conditions alone; it is a product of their interaction with factors of the social environment, countless in number and infinitely complex in character. What we are to infer from this is, then, that the consideration of crime from the biological point of view must be directed, not to the vain quest of a specific criminal diathesis, but to the more modest aim of determining, so far as such determination is possible, the manner and degree in which modes of biological constitution, permanent or transitory, may assist or retard the environmental forces that tend to give to conduct a criminal or a non-criminal bias.

That is, in fact, the sort of inquiry which has to be made in individual cases for the practical purposes of the administration of the law, for the assessing of legal responsibility, and for the adjustment of penal treatment. And it is through the analysis of the accumulated data obtained from a multiplicity of individual inquiries on the same clinical lines that we are most likely to arrive at any just conceptions regarding the biological factors in crime.

TWO STATISTICAL FACTS OF CRIMINALITY

To a limited degree, however, this clinical method may be supplemented, and some of its results may be controlled, by another method—by the examination of certain broad statistical facts of criminality. The latter method will furnish material for some tentative conclusions of considerable value in relation to the special question with which we are here concerned—the question of the influence of mental defect on conduct. It has been shown that criminal conduct involves the same aptitudes and for the most part the same impulses as non-criminal conduct, and that it is, therefore, idle to look for a specific biological difference between these socially diverse modes of activity; but it is not inconsistent with this position to recognise that there are biological conditions which may in a certain sense predispose to crime, so that, other things being equal, these conditions will be, on the average, operative in greater degree in criminals than in non-criminals when these two social categories are considered in a general view. Thus most crime that is not professional is due to failure of inhibitory control, to inability to refrain from the immediate satisfaction of impulse, though such satisfaction conflicts with the legal standards of conduct. And this failure may obviously come about in two ways—the impulse may be unduly strong, or the power that should control and direct it may be unduly weak. These two factors—strength of impulse and power of inhibition—are constantly varying in each individual under the influence of the innumerable and complex conditions of social life, conditions so multiform and subject to such rapid change that the direct and indirect effects of their interaction defy analysis. But apart from the incalculable fluctuations arising in this way, there are other fluctuations in impulse and in inhibitory power which, as they depend on organic modifications of a more general and more stable character, can be traced in the wide movements of conduct statistics.

Age and Self-Control

One such organic condition—and a very important one—is age. And the influence of age on criminal proclivity is in fact very distinct and characteristic, whether we consider the statistics of crime in general or the statistics of particular forms of crime. As will be seen from the figures in Table I., the age of the hair. The condition may sometimes be due to a continuation of the common habit of childhood of putting anything in the mouth, as is also seen in the thumb-sucking habit in both sexes, which, if not repressed early, may persist for several years. The habit of biting the finger-nails is an expression of a similar condition, but these perversions are usually seen in families of unstable, nervous constitution, whilst no such co-relation appears to be the rule in the hair-eating habit.

Butterworth [3] states: "It is probable that the custom of young girls wearing their hair loose, flowing, and hanging over the shoulders, is an important factor in favouring the establishment of biting the hair, or passing strands through the mouth or between the teeth." An analysis of the cases shows that, as a rule, the hair-eating habit dates from the period when the hair is worn loose and long. It is well known that girls in adolescence exhibit various forms of dyscrasia, or perverted appetite, such as eating chalk, rice, indiarubber, or wood (as in a black lead pencil). A variety of reasons may be assigned for such perversions—e.g., anæmia—which condition, however, is not always present, or the more active metabolic processes of the early years of adolescence in females. Insufficient or improper food may sometimes be responsible for perversion of appetite; the eating of chalk or rice is sometimes intentional, with the object of inducing pallor, which to the mind of some young girls is attractive. In a perusal of the cases, various reasons are assigned by the patients in explanation of the depraved appetite, but the statements throw but little light upon the pathology of the condition. It is a common sight in the poorer districts of any large community to see unkempt women chewing the ends of loose strands of hair, but probably none is swallowed, or hair-ball would be of more frequent occurrence.

The hair is probably swallowed in small masses after being twisted round the tip of the tongue, or after being pulled out by the hand. A condition of anæmia would make the extraction of hair from the scalp more easy than otherwise. Deglutition would be impossible unless the hair was first of all twisted or chewed into a mass, which probably afterwards becomes undone, and the individual hairs are caught in the mucous folds of the stomach, for otherwise expulsion of the mass from the gastro-intestinal tract would be of more frequent occurrence. The hair is gradually worked up again by the gastric movements, until at length it entirely fills and forms a perfect cast of the stomach, with prolongations in some instances through the pylorus into the duodenum, or even into the jejunum, and much less frequently into the œsophagus. (Moore's[5] case, and Knowsley Thornton's[21] case.)

Prof. Arthur Keith at the Royal College of Surgeons of England commented on the special features of the specimens reported by the writer. He referred to Hunter's contribution to the subject as described in Palmer's edition of his works, vol. iv., p. 93. Hunter, by an investigation of the lie of the hair in specimens of hair-cast, made important inferences of the gastric movements, which he showed are "regular" or definite in direction in the various parts of the organ. Prof. Keith showed in the specimens of this report that at the cardiac end the texture showed evidence of a more or less vortical movement, whilst at the pyloric end the movement is more of an onward character. The pyloric extremity of the smaller specimen is almost an exact mould of the antrum pylori, indicating that even here circular, as well as longitudinal movements, occur. These facts suggest that the stomach movements are of a more complex character than is ordinarily supposed to take place in the process of digestion.

A single hair-mass is most commonly present, but the literature includes a few instances of two or three masses of hair accurately opposed to each other by faceted surfaces, or small masses may also be found in the ileum giving rise to intestinal obstruction in some of the reported cases.

Elongation of the stomach is produced more easily than dilatation, and so the hair-ball increases more readily in length than in breadth. Gastritis is sometimes present, and ulceration and perforation of the stomach in several instances. Papillomata of the mucous membrane were present in Best's case,[15] as also in the second case (Mr. A. W. Sheen's) described by the writer. These hair-masses are of variable size, and weigh from a few ounces only, to large casts of the stomach several pounds in weight. In the literature the largest specimen hitherto reported was that of Mermet-de-Hauteville,[13] which weighed about 6 lb. The first of the two specimens now reported weighs 6½ lb., and is thus the largest on record. It is remarkable that digestion is generally so good until the hair-mass completely fills the stomach. In the first of the two cases now reported, except for occasional attacks of dyspepsia, definite disturbance of digestion had only been present for six months prior to operation, when a huge mass of hair completely filled the stomach. It is probable that the mass being compact, and of close texture, absorbs but little of the ingested food which is pressed onwards by peristalsis over the surface of the tumour from the cardia to the pylorus. When a prolongation of hair-mass plugs the pylorus, it is probable that the obstruction is occasionally removed by the displacement of the hair-mass within the stomach, for otherwise urgent symptoms would appear much earlier than is apparent from an analysis of the cases. In the late stage, when the mass is moulded to the stomach walls, the food probably passes most easily along the lesser curvature, as is suggested by the radioscopic appearances of the passage of a contrast meal. Gastric digestion must be very imperfect in cases of hair-cast, and probably digestion is almost entirely performed beyond the stomach, or else nutrition would suffer earlier, and to a greater degree, than is the rule in the majority of cases.

Clinical Course.—It is remarkable, as Butterworth[3] points out, how little the general health suffers considering the duration of the habit. Ledra-Heazlit[4] states that the stomach is exceedingly tolerant of foreign bodies, but eventually rebels when the limit of tolerance is reached. Symptoms ultimately appear, pain, vomiting, alternating attacks of constipation and diarrhœa being the rule, the breath becomes foul, anæmia, exhaustion, wasting follow, and unless the mass is removed, death takes place from inanition, as in (Bollinger's[14] case), perforation of the stomach (Best's case,[15], Ritchie's case[16]), or from intestinal obstruction when the hair-mass is in the ileum (Brewster's case[17]).

Physical Signs.—The hair may be deficient, especially in the temporal regions. The slight disturbance of vigour and of nutrition is a striking feature of the reported cases. In most instances the only abnormal physical signs are those of an abdominal tumour, which is most commonly present in the epigastrium, or extends across the epigastrium from one hypochondrium to the other. The tumour may occupy a lower position owing to gastroptosis, and when this is marked the pylorus may be in the pelvis (Russel's[18] case).

Schreiber[19] remarked upon the spontaneous displacement of the tumour as a valuable point in diagnosis, but this also occurs in other movable tumours. In the second case now reported the tumour was in the right lumbar region, but at the time of operation occupied the left lumbar region. The outline of the tumour was evident in many of the cases, as was also free movement on respiration, and on palpation in most instances, a smooth, well defined, hard, freely movable mass was found. Tenderness as a rule is slight or absent. The shape is variable, being generally rounded or oval, elongated or crescentic, or J-shaped, as in both of the cases now reported. The remarkable range of mobility is probably the most important physical sign in differential diagnosis. An indistinct fine, crackling sensation was elicited in the palpation of Harvie's[12] case, and this was readily made out under anæsthesia.

persons convicted of stack firing—a characteristic exploit of the village idiot—and in criminals of this class the proportion of defectives is over 50 per cent

It should be remarked that these figures refer to the population of a prison where insane and weak minded convicts are segregated, so that the proportion of mental defectives recorded is excessive , further, the criterion of deficiency is of very questionable validity These considerations do not, however, affect the value of the table for the purpose we have in view—namely, to show the relative frequency of mental defect in the several classes of delinquents

NO PROOF OF INHERENT MENTAL DEFECT IN ALL CRIMINALS

So far, then, the facts have been gathered that mental deficiency is much more frequent amongst convicted criminals than in the general population that it is most frequent in criminals convicted of crude impulsive offences such as arson, and that it rarely or never occurs in association with the more skilled forms of delinquency

Before we pass from this aspect of the question it may be well to point out that in what precedes we have been dealing either with criminals in the mass or with particular groups of criminals, and that the conclusions arrived at tell us nothing whatever about the mental level of any individual criminal It may seem superfluous to insist on so obvious a truth , but it is evident from much that is said and written on this subject that the fact of mental defect being relatively frequent amongst criminals has given rise to a vague notion that the criminal is, as it were, a sort of alloy of normal humanity, and that, just as every specimen of an alloy contains some base metal, though the percentage of its admixture may vary from one specimen to another, so every criminal is mentally defective, though some may be grossly defective and others only slightly so

Such a conception of the constitutional factors in crime may be accepted by a priori theorists, or by statisticians with an exaggerated view of the range of action of their analytical methods , but it is quite inconsistent with the facts of ordinary clinical experience, and in these matters it is on the results of such experience—on the critical study of individual cases—that we have to place our chief reliance

CRIMES OBVIOUSLY DUE TO MENTAL DEFECT

Turning back, then, to the consideration of this question from the clinical point of view, we note in the first place that the mental defective may commit crime through mere incapacity to realise the consequences of his acts We have a classic example of this sort in the case of the imbecile who cut off the head of a man as he lay asleep, and explained his conduct by saying that he wanted to see what his victim would say when he woke and found his head missing Similarly it is not uncommon for weak minded persons to commit serious acts of arson, apparently from no other motive than the desire to see a blaze And in many cases where defectives make murderous assaults under trivial provocation, their excessive reaction is due not only to weakness of inhibition, but also to an inability to appreciate the nature and effect of what they are doing These two factors may also be involved in the crimes of acquisitiveness to which the weak minded are very prone In sexual offences—a form of delinquency often associated with mental defect—it is more usually a question of lack of control over the sexual impulse with possibly in some instances an excessive development of that impulse, the strength of which is notoriously variable within a pretty wide range from one individual to another.

MORAL DEBILITY

So far we have referred to two psychological elements affecting criminal proclivity in the feeble minded—namely, lack of intelligence, impairing the capacity to appreciate the nature and consequences of conduct, and lack of inhibitory control involving inability to restrain and direct impulse We have now to consider another element to which much importance has been attributed in connexion with crime—the element of moral debility, of weakness or absence of moral sense

It is unnecessary to enter here upon any discussion concerning the nature and origin of moral emotion , it is enough for our purpose to recognise that the capacity for such emotion, in however slight a degree, is in fact a normal aptitude of man It is revealed in the feeling of repugnance experienced in regard to conduct which, though safe and profitable is in conflict with such moral standards as we have adopted instinctively or under the influence of training this repugnance taking the form of moral indignation when other people s misconduct is in question, of moral suffering or remorse when it refers to our own misconduct Like other mental attributes this moral sensibility varies in degree from one individual to another, and in some persons may be conspicuously feeble or entirely absent When such deficiency of moral feeling occurs in a person of vicious and criminal life, and from its association with other evidences of abnormality may be presumed to be due to an original fault of mental development we have the condition which has been termed moral imbecility

In considering the nature and criteria of this condition it has to be observed in the first place that mere absence or deficiency of moral feeling in a criminal is not enough of itself to constitute the condition Probably no form of crime, for instance, demands a greater degree of moral insensibility than the crime of the treacherous poisoner, but we should not, I think, describe as a moral imbecile, in the ordinary sense of that term, a man who carried out such a crime with skill and deliberation and for purposes of personal advantage And amongst the law abiding population as well as amongst criminals it is by no means exceptional to find persons of normal or even acute intelligence who appear to have little or no moral feeling Probably most of us can count amoral persons of this sort amongst our acquaintance , and history abounds in great examples of the type A deficiency of moral feeling cannot in fact be considered as an abnormal manifestation in the same sense as we may consider a defect of intelligence In the present stage of human evolution we can hardly assume that a high development of ethical sensibility, any more than a high development of æsthetic sensibility, is an essential element in our conception of the average citizen Whatever be the origin of the moral sense, it is assuredly not a necessary factor in the adaptation of the individual to his environment in the same way and to the same degree as is the intelligence—even the moral enthusiast must admit that in the struggle for existence a lack of ethical feeling may often be an advantage, while a lack of brains is almost always a drawback

The moral imbecile, then, is not simply an amoral person , he is an amoral person who presents also some degree of intellectual deficiency , he is a defective whose congenital debility is more predominant, indeed in the sphere of the emotions and the will, but affects also, to however slight an extent, the sphere of intelligence

LEGAL INTERPRETATION OF MORAL IMBECILITY.

This, no doubt, is what is meant to be conveyed in the legal definition of moral imbecility—for we have a statutory definition and not a particularly felicitous one, of this condition laid down for us in the Mental Deficiency Act of 1913 According to the first section of that Act, moral imbeciles are “persons who from an early age display some permanent mental defect, coupled with strong vicious or criminal propensities on which punishment has had little or no deterrent effect ”

This definition is open to the obvious criticism that it seems to suggest, though it does not clearly assert, that the moral imbecile must show indications of permanent mental defect over and above what may be inferred from his incorrigible addiction to ways of and the particular features of the tumour are almost peculiar to hair-mass, and if suspected, and radiographic methods be used in a routine way, then no difficulty should be experienced in the diagnosis of hair-mass of the stomach.

The free mobility of the stomach with the enclosed mass, and of the latter within the stomach as made out by “ radioscopic palpation ” (Barclay and Ramsbottom[7]) during fluoroscopic examination are characteristic of hair-mass. These observers in their valuable report state †: “ By means of palpation, it was easy to demonstrate that it was freely movable within the stomach. The tumour could be displaced, the top of it rising above the level of the bismuth food, and showing as a rounded shadow in the clear air space in the fundus of the stomach. (The ‘ magenblase ’ of Clairmont and Handek.[8]) In order to demonstrate the nature of the tumour still more clearly, the fundus of the stomach was distended with CO_2, and into a larger gastric vesicle thus obtained the hair-ball was pushed up. It gave a heavy shadow because of the coating of bismuth it carried up with it.”

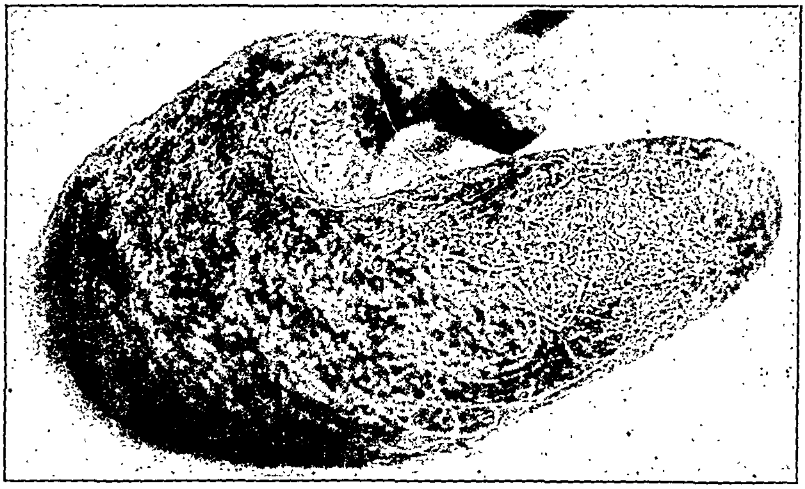

FIG. 3.—Hair-cast (Case 2). Weight 3½ lb., length along greater curvature 21½ inches, plus appendage of 7 inches. Greatest circumference 11 inches. Note the moulding at the pyloric end.

(2) A history of hair-eating is seldom obtained, even on inquiry in suspected cases. This is probably due to the fact that the habit is for the most part unconscious, for when shown the hair-mass afterwards admission of the habit is usually obtained.

(3) Small masses of hair may be passed per rectum. (Cases reported by Stover[20] and Thornton.[21])

(4) Lavage of the stomach may bring up a few strands of hair. In Paton’s case, the diagnosis was suggested whilst the patient was under observation by the doctor’s cat vomiting a small hair-ball.

(5) The presence of fatty, acid plates and needles in the contents of the fasting stomach. (Hausmann.[10])

CASE 1.—Mrs. E. P., aged 34. *History.*—She had always enjoyed good health until six months before admission to the hospital, when her lower limbs became swollen ; and soon afterwards she observed her abdomen to be swollen, and it continued to increase in size afterwards. She also suffered from breathlessness and palpitation on exertion. Indigestion had been present for some years, but lately this had taken the form of pain and vomiting after meals, with a streaky hæmatemesis on a few occasions. A few days before admission to the hospital the upper limbs had become swollen ; and of late headache and sleeplessness were troublesome features. Amenorrhœa had been present for eight months, and for some time previously menstruation had become irregular and scanty. The urine of late had diminished in amount and passed with a little difficulty. The bowels were freely opened with a tendency to diarrhœa. She had three healthy children, the youngest being 1 7/12 years.

Family History.—Unimportant, and the patient had never shown any sign of unsoundness of mind.

Condition on Admission.—The patient was first seen in the gynæcological out-patient department, King Edward Hospital, by Dr. E. Tenison Collins, as an unusual form of pregnancy was believed to be present by the practitioner in charge of the case. Dr. Collins passed the case on to the medical out-patient department, with the remark, “ the tumour is a peculiar one, but it does not belong to my department.” The woman was somewhat sallow, and showed a moderate degree of œdema of the limbs, and was fairly well nourished. The mental condition appeared to be normal. The tongue was slightly furred ; the teeth were deficient and carious. The breath was not fœtid. Heart and lungs—normal. The abdomen was distended, and on palpation was found to be occupied by a large mass extending downwards from the left hypochondrium, across and below the umbilical region and upwards to the right costal margin. The shape was crescentic with a sharp depression on its upper surface. The outline was definite ; the surface hard and smooth and free from tenderness. The mass was freely movable in all directions, and pain was entirely absent in manipulation. The normal splenic dullness was present, and merged at the costal margin into that of the mass. The urine was of specific gravity 1020, and except for being high coloured was otherwise normal.

Diagnosis.—This was indefinite, as one recognised that the features were unusual, and did not appear to belong to any known clinical entity. *A label had to be given to the* condition for the purpose of immediate admission to the hospital. A provisional diagnosis of splenic anæmia was made, but with much doubt, as the only point of resemblance to splenomegaly was the sharp depression on the mass superiorly, with a slight degree of anæmia. The patient was admitted to a medical ward, and afterwards transferred for operation under care of Mr. Cornelius Griffiths.

Progress. — In the ward the idea of pregnancy was revived by the house surgeon, who states : “ External ballottement is obtained, and hard parts can be felt per abdomen and are firm and rounded, and are all connected and can be freely moved, apparently in a fluid sac. No fœtal heart sounds can be heard, and no fœtal parts can be definitely made out.”

The case excited a great deal of interest, and almost everyone differed in opinion. Mr. Griffiths suggested that the condition was a tumour of the stomach. A moderate degree of secondary anæmia was present.

The radiographic report was as follows : Examination required— ? fœtus.

Report.—“ Shows no definite shadow. A fœtus does not show in utero.”

The radiographer—Dr. Owen Rhys—was not asked to make an examination of the stomach, or the true nature of the case may have been discovered. This case, as well as the second described in the present report, occurred in 1912, and so prior to the contributions of Thurstan Holland and others mentioned in preceding paragraphs. The general state was well maintained over a period of 14 days prior to operation, but vomiting, at first slight, became more marked, especially in the evenings. The bowels on an average were opened three times daily without an aperient, but on a few occasions a simple enema was necessary. The urine was at times scanty, and varied from 4 oz. to 32 oz. daily, and except for an excess of pigment and mucus was free from abnormality.

Operation.

The operation was performed by Mr. Griffiths.

Laparotomy.—4½ inch incision over the right rectus muscle. The stomach was found to be enormously dilated and filled by a compact mass of hair, which formed a perfect cast of the outline of the stomach and pylorus. All other organs were found to be normal.

Weight of the hair-ball on removal—6½ lb. Length along its greater curvature—24½ inches or 62 cm. ; and its greatest circumference was 12½ inches or 31·3 cm.

The superficial hairs varied from 6 to 12 inches in length, and were dark in colour and similar to those of the patient. The mass was thickly covered with a slimy, foul-smelling vided that on conviction by a court of competent jurisdiction of any person of any criminal offence punishable in the case of an adult by penal servitude or imprisonment, the court, if satisfied that such prisoner is a defective, may make any order that a judicial authority under the Act may make, or may remit the case to a judicial authority. And the section provides that the same procedure may be followed in the case of children who are liable, under the Children Act, 1908, to committal to a certified industrial school, and also in the case of persons found to be amenable to the Inebriates Acts.

---

† A little manipulation and rotation of the patient quickly demonstrated that the mass displacing the bismuth (showing as lighter area in the middle of the dark shadow of the) was actually *within* the stomach.

The court may act either on the evidence given during the trial or other proceedings, or may call for further medical or other evidence. Clause 5 of the section lays down that when it appears to the police authority that any person charged with an offence is a defective, they shall communicate with the local authority, and it shall be the duty of the police authority to bring before the court such evidence as to his mental condition as may be available.

It will be observed that these provisions of the Mental Deficiency Act do not apply to persons charged with capital crimes—that is to say, with murder or treason. Defectives indicted for these crimes are dealt with under the ordinary law, and, if the offence is proved, are either found guilty and sentenced to death, or are found guilty but insane and ordered to be detained during His Majesty's pleasure. In practice, the final result is much the same, as adequate evidence of mental deficiency, even if it does not secure a verdict of guilty but insane, will lead to reprieve, and other provisions of the Mental Deficiency Act give power to the Secretary of State to transfer mental defectives from prisons and criminal lunatic asylums to institutions for defectives.

The courts have hardly as yet made sufficiently extensive use of their powers under Section 8 of the Act to establish any large body of precedents, but so far it does not appear that medical evidence regarding mental deficiency in criminal cases will be likely to present any special difficulties. Here, as in medico-legal practice generally, the guiding principle for the medical witness should be to confine himself to his technical rôle, to make sure by exhaustive examination of the case that he is acquainted with all the relevant data, and to advance no opinion that he cannot support by facts.

HAIR-BALLS OR HAIR-CASTS

OF THE STOMACH AND GASTRO-INTESTINAL TRACT.

A REPORT* OF TWO CASES OF HAIR-CAST OF THE STOMACH, WITH AN ABSTRACT OF 108 CASES.

BY IVOR J. DAVIES, M.D. LOND.,
M.R.C.P. LOND.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, KING EDWARD'S HOSPITAL, CARDIFF.

Synonyms.—Hair-ball, hair-cast, hair mass, trichobezoar or phytotrichobezoar, tumeur pileuse.

Historical.—The condition is a rarity, but is more frequent than is generally supposed; 108 cases have been reported since Baudamant[1] described the first specimen in the literature in the *Journal de Médecine* in 1779. It is probable that unreported cases occur not infrequently in the surgical practice of all large hospitals, which, as Matas[2] suggests, would, if described, swell the statistics very considerably. In recent years several cases have been reported, and much care has been taken in a research of the literature, with the result that a careful analysis of the cases has shown the condition to be almost an entity, for there is a close uniformity of feature in the reports.

We owe much to the excellent contributions of Butterworth,[3] Ledra Heazlit,[4] Matas,[2] Moore,[5] in America, and to Thurstan Holland,[6] Barclay and Ramsbottom[7] in England, Clairmont and Haudek,[8] Huttenbach,[9] Hausmann,[10] and others on the continent. Radiography has proved to be a most valuable aid in diagnosis, as in gastro-intestinal diseases generally.

The term "bezoar" is probably of Arabian origin, being derived from the word "badzehr"; bezoar stones in ancient times were regarded with veneration as remedies against snake poison, plague, leprosy, epilepsy, dysentery, and many other maladies. Dechambre in the "Dictionnaire Dechambre" gives an excellent historical summary, and more recently Burchard[11] presents their X ray relations in a most interesting and valuable contribution to the subject.

Sir Norman Moore, President of the Royal College of Physicians of London, was greatly interested on seeing the specimens, and very kindly gave me the following historical reference from Freind's "History of Physick" (Vol. II., pp. 106 to 108, Avenzoar's account).

> "In speaking of a Jaundice, which he supposes was occasion'd by Poison, he orders three barley corns weight (not three grains as some have told us) of Bezoar: the first time I find it used by way of medicine, or any history of it described. His description of it is this: 'That is the best, which is found in the East, near the eyes of Stags. Great Stags, in those countries, eat serpents to make them strong. And before they have received any hurt from them, run to the streams of water, and go into it so far, till it comes up to their heads; this custom they have from natural instinct; and there they continue without tasting the water, (for, if they should drink it, they would die immediately) 'till their eyes begin to trickle: this liquor, which there oozes out under the eyelids, thickens and coagulates, and continues running, 'till it increases to the bigness of a chestnut, or a nut. When these Stags find the force of the Poison spent, they come out of the water, and return to their usual haunts: and this substance, by degrees, growing as hard as a stone, at last, by their frequent rubbing it, falls off. This is the most useful Bezoar of all.' And this account here given by Avenzoar is confirmed by other Arabian writers, who have travelled into Persia and China, where it most abounds. The Author of the book concerning Simples, ascribed to Serapion, erroneously supposes that it grows in some Mines: and to shew the exorbitant value of it, he quotes Abdalanarack as a voucher, that the Palace of Corduba had been given for one of these Stones. Some of the moderns will not allow the Bezoar of Avenzoar to be the same, which has gone under that name in these latter Centuries; because this, according to the best account of the most knowing Naturalists, is always found in the Stomach, or rather Omasum, of the Animal they call Cervicapra. However, I cannot but think, that our Author must mean the same thing though he differs in the account of the place, where it is formed."

Incidence.—Moore[5] states "that the incidence of bezoars or hair-balls in the human stomach might well be used as an argument in favour of evolution, as they are frequently found in animals in the season when the hair is shed, and but rarely give rise to serious symptoms, as they are frequently expelled by vomiting, or passed in the fæces with a thick coating of food particles."

In human beings the hair-eating habit is generally confined to young females, and generally dates from childhood, and has been seen even in creeping children (Harvie[12]). Butterworth[3] remarks "that few cases of trichobezoar are found in German literature, and the habit of hair-eating appears to be more prevalent among the English-speaking people," which has led Bussell to remark that "the eating of hair seems to be a favourite pastime of English women."

Pathology.—The ætiology of the hair-eating habit is probably due to some factor which is peculiar to young females in the adolescent period of life. The causation is generally ascribed to a perverted appetite, but the exact nature of the underlying disturbance is obscure. In only a small number of the cases was insanity present; in these the foreign body usually consisted of a mixture of hair and other material, such as nails, tacks, pieces of wood, and various other substances. Occasionally cotton (with a pin and hook, as in the second of the cases in the present report) or bits of string or wood form a nucleus for

* Read before the Clinical Section, Royal Society of Medicine, on April 8th, 1921.

TREATMENT OF SYPHILIS BY INTRAVENOUS INJECTIONS OF MERCURY.

By J. ERNEST LANE, F.R.C.S.,
SURGEON TO ST. MARY'S HOSPITAL AND TO THE LONDON LOCK HOSPITAL.

THE treatment of syphilis by intravenous injections of mercury was introduced in this country at the Male Lock Hospital in 1895, and in the following year I read a paper on the subject at the Third International Congress of Dermatology held in London, an abstract of which appeared in THE LANCET of Dec. 12th, 1896. The number of cases then brought forward was 76, all of them males, and the number of injections administered was over 1000. I then employed a 1 per cent. solution of cyanide of mercury, the dosage of which was ♏ xx., at first given on alternate days, but later more frequently; the number of injections varied from 46 downwards, but in at least 10 cases the treatment had to be discontinued owing to the difficulties of finding a suitable vein, or at the patient's own request.

In my experience, this treatment was more rapid in its effects than any other method of mercurial administration, painless in comparison with intramuscular injections, and perfectly safe; the only objection I then brought forward was the difficulty occasionally experienced in introducing the hypodermic needle into a vein. The treatment did not for the most part commend itself to the members of the Venereal Diseases Section of the Congress owing to its inherent difficulties, and although its critics were not hostile, they were by means enthusiastic in its favour.

Reintroduction of the Treatment, and its Application to Women.

I did not persevere much with this treatment after 1896 for various reasons, one being that I was shortly afterwards transferred to the charge of the patients in the Female Lock Hospital, and I did not think at that time that women would be suitable subjects for intravenous injections owing to difficulties with their veins; another reason was the introduction at about that time of arsenical compounds which were then coming into vogue. In 1917, finding that my patients at the Female Lock Hospital rather welcomed and looked forward to their injections of salvarsan substitutes, and that the difficulty of intravenous injections in women had been greatly over-estimated, I decided to give the treatment a further trial, the results of which have been perfectly satisfactory. The number of women I have now treated amounts to 166, of whom 40 were pregnant, mostly in the early stage; the routine adopted was one injection of one of the salvarsan substitutes and five injections of the cyanide solution per week: the doses of the latter varied with the tolerance of the patient, and it was found that many patients could stand a dosage of 40 to 50 minims, so that they received 200 to 250 minims in the course of a week. The maximum number of cyanide injections given was 110, in a case of very severe and distiguring frambœsiform syphilide of the nose and face; in 16 cases over 50 injections were given, and in 13 cases 40 or more, and the average number given came out a little under 40; the total number amounted to considerably over 5000. The strictest attention was paid to the hygiene of the mouth, and the occurrence of severe gingivitis or other manifestations of mercurialism was rare, so that under appropriate treatment the injections had seldom to be interrupted for more than a few days; in two cases phlebitis and occlusion of the veins occurred, and necessitated the recourse to other forms of mercurial treatment. Of the 126 non-pregnant women, 82 had a positive Wassermann reaction (W.R.) on admission, and a negative one on their discharge; 30 had a positive reaction on their admission, and also on their discharge, free from all symptoms; the remainder had a negative reaction both on admission and discharge, owing in some cases to the test having been performed before the evolution of the disease, and in others as the result of treatment before admission. Of the 40 pregnant cases, the W.R. was positive in 37 on admission, and negative in 3; of the babies born of these women 36 gave negative W.R.'s at birth, and remained negative until they and their mothers were discharged from hospital free from symptoms. In two cases the W.R. was positive at birth, but was rendered negative by treatment. Two cases of macerated fœtus occurred at about seven months; one infant died of cyanosis and vomiting in 24 hours, one of jaundice in a fortnight, and one at two months of diarrhœa and vomiting. The treatment of the expectant mothers was continued up to their confinement, and was resumed shortly after; they were enjoined to suckle their babies for as long as was deemed expedient, and to present themselves and their offspring for inspection at intervals of two to three months. The average stay in hospital of these patients was about 16 weeks, but many of them continued their treatment as out-patients, and the remainder resumed their ordinary avocations.

Use of the Treatment in France.

Since my reintroduction of this treatment in 1917 I found that it had been strenuously advocated in France by Dr. Thibierge, of the St. Louis Hospital, as recorded in his work, "Syphilis and the Army," published in 1918. He there states his opinion that intravenous injections of cyanide of mercury are superior to all other forms of mercurial administration, and that they constitute an attacking treatment for which no "mercurial preparation suited for the treatment of syphilis in soldiers can be substituted." His plan of treatment in some respects resembles that adopted by me, but he commences with two or three intravenous injections of cyanide of mercury, then one of novarsenobenzol followed in eight days' time by a second injection of that substance; in the intervals between the novarsenobenzol injections an intravenous injection of cyanide of mercury is given daily or every other day; 12 to 15 injections in all, the course lasting from 18 to 24 days altogether. In Thibierge's opinion, if followed by regular treatment by mercurial pills it was sufficient to protect the patient from secondary disturbances.

Conclusion.

In conclusion, I am more than ever impressed with the value of intravenous injections of mercury, given concurrently with one of the salvarsan substitutes, and for the prophylaxis of syphilis I consider it to be infinitely superior to any other routine of treatment. I fully realise that it is not appropriate to the treatment of out-patients in the V.D. clinics, but I am convinced that it is the most reliable method for use in institutions where the patients can be induced to stay until the complete subsidence of all symptoms of syphilis.

For the careful records of these cases I am greatly indebted to my house surgeon. Dr. G. W. Rundle, and to Miss Ashby, matron of the Female Lock Hospital.

THE PEOPLE'S LEAGUE OF HEALTH.—Ten lectures are being given this autumn under the auspices of the League. On Oct. 13th Sir G. Sims Woodhead delivered the first lecture, and eight subsequent lectures will be delivered on Thursdays at 6 P.M. by Prof. E. Collis (Oct. 20th), Dr. W. A. Potts, Dr. Leonard Hill, F.R.S., Dr. Eric Pritchard, Mr. E. B. Turner, Mr. E. Farmer, Mr. Bishop Harman, and Dr. C. J. Bond. These lectures will be delivered at the London Day Training College, Southampton-row, W.C. The last lecture of the series will be delivered by Sir Maurice Craig at the house of the Royal Society of Arts, John-street, Adelphi, Strand, on Wednesday, Dec. 14th, at 6 P.M. The fee for the course is 4s. Further particulars may be obtained from the Honorary Organiser, Miss Olga Nethersole, at 7, Hanover-square, London, W. 1.

A sense of crackling or deep crepitation was also elicitated in Moore's[5] case

Radiography—The appearances are distinctive, and as this adjunct to diagnosis is now universally adopted in all obscure abdominal affections, the diagnosis of hair mass of the stomach should now become the rule and not the exception as formerly Thurstan Holland[6] has given us the first detailed description of the X ray appearances of hair mass, whilst Ramsbottom and Barclay[7] presented the first case which was absolutely and definitely diagnosed by radiography, and they emphasise the importance of "radioscopic palpation" in association with the *screen examination* The continental observers already named in the first section of this paper also made valuable contributions to the radiographic diagnosis of hair ball

Mr Thurstan Holland[6] has very kindly given me permission to reproduce particulars of the two cases which are of classical importance in the progress of our knowledge of the subject In the first case despite a suggestive picture, an exact diagnosis of the gastric tumour was not definitely made out, although Dr Barclay, of Manchester, suggested hair ball

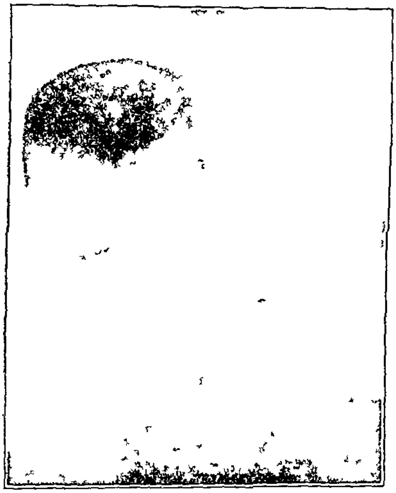

FIG 1 —Radiograph (Thurstan Holland[6]) The first mouthfuls of the opaque meals spread out to form a cap over the upper end of the tumour

An exact diagnosis was definitely made in the second case prior to operation The patient was a girl of 16 years, with a history of a large abdominal tumour for ten years which at various times had been diagnosed as a tumour of the spleen liver, or kidneys Operation was refused as no definite diagnosis was made For five or six years, "up to a year ago," there had been a constant vomiting of food This had stopped a year ago but lately had commenced again There was no pain but some tenderness in the upper right abdomen The tumour presented itself as a large hard mass curving down from below the left costal margin to a point below the umbilicus and then upwards to the right to disappear under the lower edge of the liver The tumour was freely movable and when grasped by its lower part could be swung from side to side of the abdomen as if suspended from a fixed point behind the upper left costal margin.

Mr Holland[6] states "with a vivid recollection of my first case the diagnosis appeared quite certain and I made a definite diagnosis of hair ball in the stomach before the X ray examination The history was then discussed more fully with the mother and the fact elicited that no one had ever suggested to her any other diagnosis except that of 'tumour of the liver spleen or kidneys'—these were the mother's own words I then asked a direct question *Are you sure that no one has ever suggested to you that the tumour consisted of hair?* The answer was significant 'No But now that you mention hair I remember that when she was 4 or 5 years of age she used *not only* to bite off her own hair, but also in her sleep to pick off and chew bits of blanket &c'

"The radiographic appearances were interesting and characteristic —

"(1) Before any food was given it was possible to make out the general shape of the tumour on the screen and to differentiate it from the liver as it was thrown into relief by the gas-distended transverse colon A plate was taken *which clearly showed this* The gas distended transverse colon partly encircled the dark shadow of the hair-mass which almost completely filled the stomach *This localises* the gastric area and excludes the spleen and omentum as these are outside the colonic loop The liver can usually be distinguished from *the stomach area* by a faint darker outline (Matas[3])

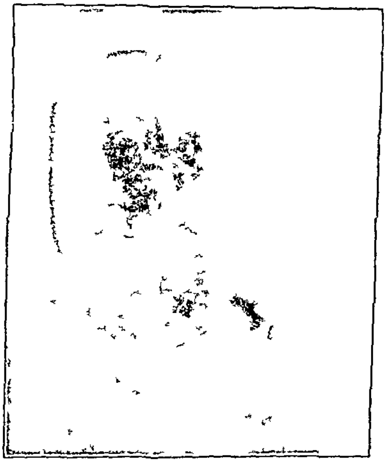

FIG 2 —Radiograph (Thurstan Holland) The appearance of the tumour when covered by the contrast meal Note the *gas-distended transverse colon* encircling the lower end of the tumour

"(2) The first few mouthfuls of a liquid barium meal remained held up in the *cardiac* end of the stomach and spread out as if forming a cap to something inside the organ (See radiograph, Fig 1)

"(3) Shortly *after* swallowing a breakfast cupful of the food the whole stomach was mapped out by what was obviously the barium lying between *the walls of the stomach and the mass filling it*

"*It was then obvious that an enormous mass—the hair-ball—filled the entire stomach right up to the pyloric end, the J shape* being most beautifully shown

Mr Newbolt removed a large hair-ball [illegible] lb 15 oz in weight two days later The patient made an excellent recovery The radiographs were taken in a standing position with a *16 inch coil* and a Sanax break The exposure in each case was approximately half a second an Ilford plate and an intensifying screen being used

Diagnosis—(1) This is now mainly one of differentiation of gastric tumour, and for all practical purposes lies between malignant disease and hair-mass The early age, sex, long history, good health

TREATMENT OF SYPHILIS BY INTRAVENOUS INJECTIONS OF MERCURY.

BY J. ERNEST LANE, F.R.C.S.,
SURGEON TO ST. MARY'S HOSPITAL AND TO THE LONDON LOCK HOSPITAL.

THE treatment of syphilis by intravenous injections of mercury was introduced in this country at the Male Lock Hospital in 1895, and in the following year I read a paper on the subject at the Third International Congress of Dermatology held in London, an abstract of which appeared in THE LANCET of Dec. 12th, 1896. The number of cases then brought forward was 76, all of them males, and the number of injections administered was over 1000. I then employed a 1 per cent. solution of cyanide of mercury, the dosage of which was ♏ xx., at first given on alternate days, but later more frequently; the number of injections varied from 46 downwards, but in at least 10 cases the treatment had to be discontinued owing to the difficulties of finding a suitable vein, or at the patient's own request.

In my experience, this treatment was more rapid in its effects than any other method of mercurial administration, painless in comparison with intramuscular injections, and perfectly safe; the only objection I then brought forward was the difficulty occasionally experienced in introducing the hypodermic needle into a vein. The treatment did not for the most part commend itself to the members of the Venereal Diseases Section of the Congress owing to its inherent difficulties, and although its critics were not hostile, they were by means enthusiastic in its favour.

Reintroduction of the Treatment, and its Application to Women.

I did not persevere much with this treatment after 1896 for various reasons, one being that I was shortly afterwards transferred to the charge of the patients in the Female Lock Hospital, and I did not think at that time that women would be suitable subjects for intravenous injections owing to difficulties with their veins; another reason was the introduction at about that time of arsenical compounds which were then coming into vogue. In 1917, finding that my patients at the Female Lock Hospital rather welcomed and looked forward to their injections of salvarsan substitutes, and that the difficulty of intravenous injections in women had been greatly over-estimated, I decided to give the treatment a further trial, the results of which have been perfectly satisfactory. The number of women I have now treated amounts to 166, of whom 40 were pregnant, mostly in the early stage; the routine adopted was one injection of one of the salvarsan substitutes and five injections of the cyanide solution per week; the doses of the latter varied with the tolerance of the patient, and it was found that many patients could stand a dosage of 40 to 50 minims, so that they received 200 to 250 minims in the course of a week. The maximum number of cyanide injections given was 110, in a case of very severe and disfiguring framboesiform syphilide of the nose and face; in 16 cases over 50 injections were given, and in 13 cases 40 or more, and the average number given came out a little under 40; the total number amounted to considerably over 5000. The strictest attention was paid to the hygiene of the mouth, and the occurrence of severe gingivitis or other manifestations of mercurialism was rare, so that under appropriate treatment the injections had seldom to be interrupted for more than a few days; in two cases phlebitis and occlusion of the veins occurred, and necessitated the recourse to other forms of mercurial treatment. Of the 126 non-pregnant women, 82 had a positive Wassermann reaction (W.R.) on admission, and a negative one on their discharge; 30 had a positive reaction on their admission, and also on their discharge, free from all symptoms; the remainder had a negative reaction both on admission and discharge, owing in some cases to the test having been performed before the evolution of the disease, and in others as the result of treatment before admission. Of the 40 pregnant cases, the W.R. was positive in 37 on admission, and negative in 3; of the babies born of these women 36 gave negative W.R.'s at birth, and remained negative until they and their mothers were discharged from hospital free from symptoms. In two cases the W.R. was positive at birth, but was rendered negative by treatment. Two cases of macerated fœtus occurred at about seven months; one infant died of cyanosis and vomiting in 24 hours, one of jaundice in a fortnight, and one at two months of diarrhœa and vomiting. The treatment of the expectant mothers was continued up to their confinement, and was resumed shortly after; they were enjoined to suckle their babies for as long as was deemed expedient, and to present themselves and their offspring for inspection at intervals of two to three months. The average stay in hospital of these patients was about 16 weeks, but many of them continued their treatment as out-patients, and the remainder resumed their ordinary avocations.

Use of the Treatment in France.

Since my reintroduction of this treatment in 1917 I found that it had been strenuously advocated in France by Dr. Thibierge, of the St. Louis Hospital, as recorded in his work, "Syphilis and the Army," published in 1918. He there states his opinion that intravenous injections of cyanide of mercury are superior to all other forms of mercurial administration, and that they constitute an attacking treatment for which no "mercurial preparation suited for the treatment of syphilis in soldiers can be substituted." His plan of treatment in some respects resembles that adopted by me, but he commences with two or three intravenous injections of cyanide of mercury, then one of novarsenobenzol followed in eight days' time by a second injection of that substance; in the intervals between the novarsenobenzol injections an intravenous injection of cyanide of mercury is given daily or every other day; 12 to 15 injections in all, the course lasting from 18 to 24 days altogether. In Thibierge's opinion, if followed by regular treatment by mercurial pills it was sufficient to protect the patient from secondary disturbances.

Conclusion.

In conclusion, I am more than ever impressed with the value of intravenous injections of mercury, given concurrently with one of the salvarsan substitutes, and for the prophylaxis of syphilis I consider it to be infinitely superior to any other routine of treatment. I fully realise that it is not appropriate to the treatment of out-patients in the V.D. clinics, but I am convinced that it is the most reliable method for use in institutions where the patients can be induced to stay until the complete subsidence of all symptoms of syphilis.

For the careful records of these cases I am greatly indebted to my house surgeon, Dr. G. W. Rundle, and to Miss Ashby, matron of the Female Lock Hospital.

THE PEOPLE'S LEAGUE OF HEALTH.—Ten lectures are being given this autumn under the auspices of the League. On Oct. 13th Sir G. Sims Woodhead delivered the first lecture, and eight subsequent lectures will be delivered on Thursdays at 6 P.M. by Prof. E. Collis (Oct. 20th), Dr. W. A. Potts, Dr. Leonard Hill, F.R.S., Dr. Eric Pritchard, Mr. E. B. Turner, Mr. E. Farmer, Mr. Bishop Harman, and Dr. C. J. Bond. These lectures will be delivered at the London Day Training College, Southampton-row, W.C. The last lecture of the series will be delivered by Sir Maurice Craig at the house of the Royal Society of Arts, John-street, Adelphi, Strand, on Wednesday, Dec. 14th, at 6 P.M. The fee for the course is 4s. Further particulars may be obtained from the Honorary Organiser, Miss Olga Nethersole, at 7, Hanover-square, London, W. 1.

mucus together with flakes of a sebaceous or adipocere material The stomach wall was hypertrophied and its mucous membrane showed a condition of gastritis in places and also areas denuded of epithelium having a glistening appearance similar to that of leukoplakia X ray examination disclosed no foreign bodies within the hair mass

The patient bore the anæsthetic and operation well but an hour later collapsed and despite energetic stimulation died

Remarks

On inquiry from the relatives no history of mental deficiency or of hair eating was obtained The hair on the scalp was scanty, but no importance was attached to this fact and afterwards the nurse in charge of the case stated that the patient on one occasion made the following remark ' I used to have a lot of hair and have lost it My hair used to be below my waist—now look how short it is She volunteered no further information but if the above remark had been reported by the nurse it is possible that a suspicion of the true condition may have occurred to one of us

The house surgeon in his note made an important observation which although wrongly interpreted was a correct impression of the free movement of the mass on palpation He remarked upon the free movement of the mass apparently in a fluid sac The most striking impression obtained from the published records of hair ball of the stomach is the free mobility of a hard smooth mass on manipulation If this fact is borne in mind then the possibility of hair ball will be remembered and a diagnosis can afterwards be definitely established by radiography

CASE 2—Mrs M E aged 33 Admitted to the King Edward Hospital Cardiff under care of Mr A W Sheen

History—The patient was quite well up to three years ago when she noticed a lump on the right side of the abdomen which gradually got larger A year later she suffered at intervals from morning vomiting but never after meals Occasional slight pain was felt in the swelling At times the lump appeared to get smaller with the passage of an increased amount of urine

Previous Health—Good except for a temporary mental disturbance of six months duration a twelvemonth prior to operation from which she appears to have made a complete recovery Four healthy children

Family History—Unimportant

Present Condition—A healthy looking well nourished woman Heart and lungs normal On abdominal examination a hard rounded smooth movable painless lump was found in the right lumbar region but which did not appear to fill the loin A dull note was obtained on percussion but non continuous with the liver dullness

Operation performed by Mr Sheen eight days later The abdomen was opened by a longitudinal incision on the right side but the mass was now situated in the left lumbar region and found to be a hard movable body within the stomach A 4 inch longitudinal incision was made in the most avascular part of the anterior surface of the stomach and a characteristic hair cast of the organ with a prolongation into the pylorus and duodenum was removed The stomach wall was hypertrophied The hair mass was 21¼ inches or 54 3 cm in length along its greater curvature and 11 inches or 27 cm in its greatest circumference the appendage withdrawn from the pylorus being 7 inches or 17 cm in length The weight was 3¼ lb A few adherent strands of cotton were seen on its surface also a hook similar to that shown in the interior on subsequent X ray examination (Fig 3) There was a large papilloma involving the lesser curvature which appeared to be of an innocent nature and also several similar smaller tumours over the antrum pylori These were removed and the raw areas sutured The usual surgical procedure was followed in the completion of the operation The patient made a full and speedy recovery, and was discharged 14 days later

A careful surgical technique is necessary during the removal of the hair mass, which is frequently in a foul septic condition Multiple hair masses in the stomach and intestines have also been reported in several instances as in the case of Ledra Heazlit [4] where two operations were performed the first for the removal of a gastric hair cast, and the second three days later for ileus owing to obstruction of the ileum by another hair mass Dr Heazlit[4] emphasises the importance of this fact being borne in mind at the time of operation In Bell s[22] case there were 11 operations in all for the removal of hair masses from the stomach and small intestine with recovery Butterworth[3] in his analysis of the subject in 1909, collected 42 cases, Moore[5] in 1914, 53 cases, Ledra Heazlit,[4] in 1914, 70 cases, and Matas,[2] in 1915, brought the number of cases to 77. These contributors in their valuable papers compiled a careful bibliography of the subject

The present paper brings the number of cases to 108, the additional references alone being recorded, except for the cases of special interest used for the purpose of illustration

My thanks are due to Dr Thurstan Holland and to my colleagues on the staff of the Cardiff Hospital

LITERARY INTELLIGENCE —Messrs J F. Lehmanns of Munich publishers of the *Münchener Medizinische Wochenschrift* announce that they have taken over the publication of the *Archiv fur Rassen und Gesellschaftsbiologie* edited by Dr Alfr Ploetz. They have also taken over the *Archiv f Biologie* edited by L. Frank, M v Frey, and E Voit

Commentary.

The first of the above cases is an excellent example of what may be termed silent renal tuberculosis—one of the conditions which should always be borne in mind in any obscure abdominal affection associated with progressive loss of flesh and strength; owing to the absence of the cardinal symptoms of urinary disease it is frequently overlooked. Cystoscopy is quite as essential as an X ray examination. The favourable prognosis of nephrectomy in an early stage, when the disease is unilateral and before secondary infection has supervened, demonstrates the importance of excluding this condition.

According to Straus of Chicago there are six types of primary renal tuberculosis:—

(1) The cystitis type, where symptoms are referred to the bladder, and time is wasted in treating this locally. It is not sufficiently recognised that in men, apart from stone, stricture, and prostatic obstruction, cystitis is, to say the least, uncommon. This type furnishes 40 to 60 per cent.

(2) The renal type, where pain is referred to the kidney with attacks of renal colic, also furnishing from 40 to 60 per cent.

(3) A sudden, severe, and apparently causeless hæmaturia, furnishing 25 per cent.

(4) Stated by Straus to be very rare, a type running a course entirely symptomless, except for albuminuria.

(5) Cases running a symptomless course until a perinephric abscess supervenes.

(6) A type with fever, sweats, and rigors, due to a mixed infection.

As regards Case 2, appendicitis is not unfrequently diagnosed in cases of renal calculus and pyelitis, and these conditions should be excluded before the appendix is attacked. The last case shows the importance of remembering the possible presence of abnormal renal arteries. Eisendrath and Straus found in 200 kidneys examined 4 per cent. of true lower polar arteries, 3·5 arising from the aorta, 0·5 from the left common iliac, and altogether 14 per cent. of true accessory arteries, in addition to those pseudo-accessory arteries arising from a single renal. During any operation on the kidney requiring its delivery the unexpected presence of one of these may give the surgeon a disconcerting interlude in his manipulations, as occurred to me lately in an apparently straightforward nephrolithotomy, when in separating the upper pole of the kidney an accessory polar artery was torn across; the proximal end retracted out of sight, and the smart hæmorrhage resulting was only arrested by gauze pressure until the kidney was delivered, when the bleeding vessel could be found and ligated.

CULTIVATION OF SPIROCHÆTES

ON THE SURFACE OF SOLID MEDIA CONTAINING AN "ESSENTIAL SUBSTANCE."

BY F. W. TWORT, M.R.C.S., L.R.C.P. LOND.
(From the Laboratories of the Brown Institution, London.)

IN this investigation no attempt has been made to confirm the work of Noguchi, who has obtained what he considers to be a definite growth of spirochætes, including *Treponema pallida*, on his well-known medium under anaerobic conditions, but rather to obtain, if possible, a good surface growth on solid media in which the changes in form of the spirochætes could be better studied, and which could be used for complement-deviation tests, and for studying the problems of infection and immunity.

Working with the late Mr. G L. Y. Ingram in 1910, I succeeded in cultivating Johne's bacillus, an acid-fast bacillus allied to the lepra and tubercle bacilli, which infects the intestinal tract of cattle, sheep, goats, &c. This was done by adding to any good medium a small quantity of a certain essential food which we found to be necessary for its vitality and growth and which we found to be stored up in the bodies of allied bacteria such as the tubercle bacilli and *Bacillus phlei*. We found also that this food, which we called the "essential substance," could be extracted from *Bacillus phlei* and allied bacilli by ethyl alcohol, glycerine, &c. These results were first submitted to the Royal Society, before which body they were read in November, 1910, and given in more detail in February, 1912, being also published in the Proceedings of the Society. Further investigations on Johne's bacillus and the essential substance necessary for its growth were published later, but it will only be necessary to mention here the simplest form of the medium used. This was prepared as follows:—

Bacillus phlei was grown on 4 per cent. glycerine-peptone-beef broth. The growth was then collected, killed by steaming, and dried. One gramme of the dried bacillus was ground up with 12 c.cm. of glycerine and 22 c.cm. of normal saline. The emulsion so obtained was autoclaved, and when cool was added to 66 c.cm. of mixed yolk and white of new-laid eggs. The medium was then placed into tubes, sterilised at 61° C. on three successive days, and inspissated in slopes. In place of the saline we often used ordinary peptone-beef broth or a broth prepared with brain tissue instead of beef.

As has been pointed out, on this medium we obtained good growths of Johne's bacillus, and on one or two occasions we succeeded in getting a slight growth of the lepra bacillus of man. The medium also proved to be very good for the cultivation of the diphtheria group of bacilli. Before passing on to the consideration of spirochætes it may be noted that special nutrition substances which have since been found in various foods, and have been named vitamins—substances which are essential to the life and growth of animals and man are probably analogous substances to the essential substance in the bodies of acid-fast bacilli which we found to be necessary for the growth and multiplication of Johne's bacillus.

Results Already Obtained.

Our work has been continued with special reference to these essential substances which are not contained in ordinary laboratory media, but are essential to, or of assistance in, the growth of certain bacteria. Most of this work carried out with extracts of bacteria, seeds, fungi, and other vegetable substances has already been published in our papers on Johne's disease, and it will not be necessary to discuss these in detail here. However, the results with Johne's bacillus indicated the importance of this line of research, and attempts were made to cultivate other micro-organisms on media prepared along similar lines. The experiments with spirochætes had given one definitely positive result when the work was interrupted by the war, and I regret to say that during my absence in 1916 my culture died out; since my return I have been unable to continue the investigation owing to the difficulty of obtaining the necessary material. Under these circumstances it will not, I hope, be out of place to give the results so far obtained, incomplete though they may be. One of the media used in the primary cultures was prepared in the manner already described except that the killed growth of a diphtheroid bacillus was used in place of *Bacillus phlei*, and 3 per cent. of glycerine was used instead of 5 per cent.

The material used in the successful experiment consisted of lymphatic gland tissue obtained from a mouse that had died, a small piece being removed aseptically and placed on the surface of the medium just described. The tube was capped with gutta-percha tissue and incubated aerobically at 37° C. After nine days' incubation a delicate growth was observed round the tissue, and this proved to consist of a pure culture of a delicate spirochæte. Some difficulty was experienced in obtaining subcultures as no growth took place on fresh tubes of a somewhat similar medium in the absence of the gland tissue. Successful subcultures, however, were immediately obtained on the standard egg medium containing 1 per cent. of *B. phlei*. Further experiments showed that better growths were obtained when the egg medium was made with ordinary peptone-beef broth or peptone-brain broth in place of the saline; 1 per

FOUR GENITO-URINARY CASES

ILLUSTRATING SOME DIFFICULTIES IN DIAGNOSIS.

BY J. W. GEARY GRANT, F.R.C.S. ENG.,
HON. ASSISTANT SURGEON, KING EDWARD VII. HOSPITAL, CARDIFF.

THE following cases well illustrate the difficulties of diagnosis in certain genito-urinary conditions, and also the desirability in any obscure abdominal disease of a complete investigation of the genito-urinary system. X ray examinations, when negative, obviously only exclude such conditions as calculus, and when apparently positive still require verification of their findings by use of the cystoscope and ureteral catheter.

Tuberculous Kidney with Blocked Ureter.

CASE 1.—The patient was a police constable aged 30 of fine physique. He was admitted to King Edward VII. Hospital, Cardiff, under the care of Dr. Mitchell Stevens, complaining of progressive weakness and loss of flesh, feeling of nausea but no vomiting, and pain in epigastrium immediately after food. The doctor who sent him to hospital informed Dr. Stevens that in March of 1920 the patient came to him for an attack of pain and difficulty in micturition, and that on that occasion he passed a catheter and drew off about half a pint of muco-pus. Since that time there had been no symptoms referred to the urinary organs. In view of the history Dr. Stevens requested me to make a cystoscopic examination, and this was done on Jan. 1st, 1921. The bladder appeared perfectly normal, except that I was unable to make out any sign of a left ureteric orifice. Indigo carmine was injected; vigorous jets from the right ureter appeared in 20 minutes but none from the left. A week later cystoscopy gave the same result. Skiagraphy of the kidney region and of the stomach after an opaque meal gave a negative result. On palpation the left kidney appeared only moderately enlarged. Although the patient's symptoms at that time and for many months previously were referred solely to the stomach, a tentative diagnosis of tuberculous kidney was made; at Dr. Stevens's request, on Feb. 9th I cut down on the kidney, which was much enlarged, the fatty capsule having been converted into a fibro-lipomatous mass of the consistence of cartilage, adherent to the peritoneum and densely adherent to the diaphragm. In endeavouring to get inside Zuckerkandl's capsule, to avoid opening the peritoneum, a considerable perinephric abscess was opened into, discharging thick pus found afterwards by the pathologist to contain *Staphylococcus aureus* in pure culture. The difficulties of separating this kidney without damage to surrounding structure were enormous. The vascular pedicle, which was very short, was isolated, transfixed, tied with two mass ligatures of stout catgut and divided, the kidney delivered, and the ureter brought out at the lower angle of the wound. A tear was then found in the peritoneum, in which a small tube was inserted in case the serosa had been soiled, and the peritoneum was then sutured round this and the tube brought out through a separate stab incision. A large drainage-tube was inserted into the upper angle and the wound closed in layers. There was moderate shock, but the patient speedily rallied, and for two days appeared to be doing well. Then hiccough set in, his temperature rose to 100° and 101° F., and signs of broncho-pneumonia with increasing dullness at both bases supervened with distressing insomnia; he died on the tenth day after operation.

The kidney on its removal showed hardly a trace of normal renal tissue, the pyramids were a canary yellow with intervening green and pink patches, the pelvis a narrow slit, and the ureter obliterated. It appears to me that a year ago, when he presented urinary symptoms, there was fairly advanced tuberculous infection of the kidney; the ureter had then become suddenly blocked from tuberculous debris and the kidney ceased to secrete.

Stone in Ureter Simulating Acute Appendicitis.

CASE 2.—A housewife, aged 47, admitted at midnight to the above hospital as a case of acute appendicitis, with a history of three weeks' illness off and on and one week of acute symptoms, severe abdominal pain, vomiting, and constipation. On admission the pain was referred to the right loin passing to the groin. There was tenderness over the upper half of the right rectus and tenderness on deep pressure over the gall-bladder, but none over McBurney's point. I diagnosed acute cholecystitis and opened the abdomen by a right paramedian incision above the umbilicus. The gall-bladder and appendix were both normal. On passing the hand to the right kidney pouch the kidney was felt to be large and the pelvis distended and very tense. No stone could be felt in pelvis or ureter, and the rest of the abdomen was normal. Abdomen closed. The following day I cystoscoped the patient; urine issued normally from the left ureter, but none was seen to come from the right, and a ureteral catheter passed for 1½ inches when it was arrested. A skiagram showed two minute shadows in the situation of the lower end of the right ureter, which I believed corresponded to the point of arrest of the catheter. All symptoms then subsided. A week later I again cystoscoped her and passed a catheter to the pelvis of left kidney, and then one in the right for 1½ inches and injected sterile olive oil. I again cystoscoped her on March 1st, when a small stone of a brick-red colour, 1 cm. by 0.5 cm., was seen in the bladder, and a still smaller one in the mouth of the ureter, from which it was coaxed by the beak of the cystoscope; both were removed with a Bigelow's evacuator. The larger stone was very irregular, with numerous spicules. Had this case not come in the middle of the night as an acute abdomen it would probably have been further investigated before operation. The patient gave no history of any urinary symptoms, but as she was very deaf and not very intelligent a history was difficult to elicit.

Pain after Gastro-jejunostomy: Renal Stone.

CASE 3.—A dentist, aged about 40, operated on by me for gastric ulcer some two and a half years ago; a large horse-shoe ulcer of the lesser curvature was then found, and as the patient's condition was not very good I performed a posterior no-loop gastro-jejunostomy. He had a severe attack of ether pneumonia, but on recovery from this he left the hospital and had no further trouble, except attacks of bronchial asthma for two years; he then consulted me on account of a return of all his symptoms. I considered the possibility of the ulcer having become malignant, of a jejunal ulcer or perigastric adhesions, and I advised an exploratory laparotomy; the patient wished to try palliative treatment for a time, but found the pain intolerable, and he was taken into hospital. An X ray examination with the screen showed a "dumping stomach," the meal passing immediately through the anastomotic opening into the jejunum. At operation, except for a few adhesions, the gastro-jejunostomy appeared perfect, the jejunum passed with a gentle curve to the left with no sign of kinking, and there was no sign of jejunal ulcer; the original lesser curve ulcer appeared to have healed, with only some slight induration at its site, and a partial gastrectomy in a patient far from robust did not appear to be warranted. On examination of the rest of the abdomen on the right side a hard body the size of a walnut, evidently a stone, was felt in the lower part of the pelvis of the right kidney. It was impossible to remove it with any degree of safety from a median laparotomy wound, and this was closed. The patient again had a severe attack of ether pneumonia. On recovering from this a skiagram showed an opacity about the size of a shilling in the situation where the stone was felt at the laparotomy. He is waiting until he is in a better state of health to have the stone removed.

The case is remarkable in that he describes his pain as exactly the same as that which he had before the first operation, and refers it to the left side; nothing found at the second operation indicated that this was due to the gastric ulcer or his anastomosis. He has never complained of any urinary symptoms.

Accessory Renal Artery: ? Intermittent Hydronephrosis.

CASE 4.—A girl, aged 16, admitted to hospital March 30th, 1921, gave a history of a sudden attack of severe pain in the hypogastrium in February, with pain across the small of the back, coming on after micturition. Extreme nocturnal and diurnal frequency and hæmaturia for 14 days. Her own doctor diagnosed vesical calculus, and sent her to Dr. Mitchell Stevens, who diagnosed calculus in the left kidney or ureter. On admission no pain, frequency, or hæmaturia; a skiagram showed a shadow, the size of a shilling and very well defined, situated just to the outer side of and below the transverse process of the first lumbar vertebra (left). A second plate a week later showed the same, as also one taken after her operation. On cystoscopy the bladder and the ureteric orifices were normal, and urine came from each. I, however, failed to get a catheter to enter the left. On April 13th I exposed the left kidney and could find nothing resembling a stone in the kidney, pelvis, or ureter, or anything which corresponded to the shadow found in the plate. There was, however, an accessory renal artery to the lower pole passing behind the ureter at its junction with the pelvis of the kidney, and this I divided between ligatures. Possibly this abnormal polar artery caused an intermittent hydronephrosis with hæmaturia. Kidd and Ransohoff state that hæmaturia, often profuse, may follow temporary occlusion of the ureter in intermittent hydronephrosis.

was adopted. The diameter of the test tubes is of importance; half inch diameter tubes were employed. Readings were taken after 24 hours and results ranging from complete coagulation to slight increase in viscidity were recorded as positive. The test was carried out on 261 serums.

From the table it will be seen that only 43 per cent. of the serums giving a positive W.R. showed a positive formalin test, and that 9·5 per cent. of serums giving a negative W.R. gave a positive formalin test.

The Sachs-Georgi Reaction.

It was pointed out in 1910[2] that extracts of various organs gave a slight precipitate when added to syphilitic serum. The precipitate was, however, found to be inconstant, and was therefore considered of little diagnostic value. In 1918, Sachs and Georgi[3] called attention to the fact that the addition of a solution of cholesterol to alcoholic heart extract made a good antigen for a precipitation test. The precipitate was claimed to be definite and constant in cases of syphilis. The antigen employed in the following series was that recommended by Taniguchi,[4] which is practically identical with that of Sachs and Georgi, and consisted of 20 parts of 10 per cent. alcoholic heart extract, 10 parts of absolute alcohol, and 1 part of 1 per cent. alcoholic solution of cholesterol. This was rapidly mixed with an equal volume of saline and allowed to stand for 15 minutes. The mixture was then rapidly diluted with twice its volume of saline.

The method adopted for the test was that recently described by Taniguchi.[4] Four tubes were used for each serum, three containing respectively 0·025, 0·05, and 0·1 c.cm. of serum to be tested, each made up to 1 c.cm. with saline and 0·5 c.cm. of diluted antigen added. The fourth tube was a serum control and contained 0·05 of serum made up to 1·5 c.cm. with saline and sufficient alcohol to give the same alcohol dilution as obtained in the other tubes after adding the antigen—namely, 1 in 18. The addition of this small quantity of alcohol here serves a dual purpose: it inhibits the growth of organisms which might otherwise occur, and causes some precipitation of proteins from the diluted blood serum, which by comparison aids in distinguishing between a non-specific and a slightly positive result. With each batch of serums positive, negative and antigen controls were carried out. The tubes were incubated for 24 hours at 37° C. in accordance with Sachs and Georgi's later experience.[5] It is possible to read the results immediately, but if the tubes be allowed to stand for an hour at room temperature after being removed from the incubator the flocculation becomes better marked. The reaction was carried out on 252 serums.

The results were read (+ + + +), (+ + +), (+ +), (+) and (—) according to the amount of flocculation present in the tubes. As is the case of the W.R., some reactions occurred in which the tube containing 0·1 c.cm. of serum would be slightly positive and those containing 0·05 c.cm. and 0·025 c.cm. strongly positive. With the W.R. such results are a rarity, but with the S.G. test they are met with some frequency. The great difficulty encountered in reading the results was to distinguish between a weak positive (+) and the slight pseudo-flocculation given by some negative serums—a point which is well illustrated by Table I. When all the S.G. results read as positive—i.e., (+ + + +) to (+) inclusive—are included, the number of cases giving a positive W.R. which also gave a positive S.G. test is 95·5 per cent. of the total positive W.R.'s. The ratio of the negative results, however, is not so good. If (+ + + +), (+ + +), and (+ +) are considered as positive, and cases giving (+) only are included with the negative results, the number of cases giving a negative W.R. and a negative S.G. is 97 per cent. of the total negative W.R.'s, but the proportion of the positive results is poor.

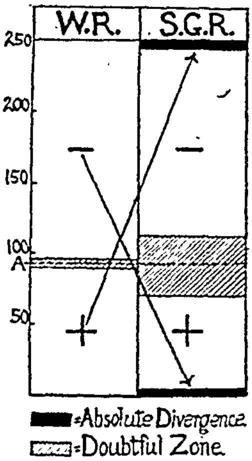
TABLE I.

Test.		Number of cases.						Percentages.		
Wassermann reaction		+	+	—	—	Partial positive.	Partial positive.	Wassermann and new test agree.	Ratio of pos. W.R. and pos. new test to pos. W.R.	Ratio of neg. W.R. and neg. new test to neg. W.R.
New tests		+	—	—	+	+	—			
Formalin test (261 cases) ..		42	56	142	15	2	4	72	43	90·5
Sachs-Georgi reaction[1] (252 cases)	Taking (+ + + +), (+ + +), (+ +), and (+) as positive	87	4	129	26	2	4	88	95·5	83·5
	Including (+) with the negative results	70	21	150	5	1	5	89·5	77	97

In calculating percentages the cases showing a doubtful Wassermann reaction have been omitted. The Wassermann reactions were carried out by the Fildes and McIntosh technique.

Table II. is a graphic representation of the results. The blocked areas indicate complete divergence of the test—i.e., positive W.R. with absolutely negative S.G. reactions, or vice versa. The shaded areas indicate a "positive incomplete" or "negative trace" result in the W.R. and a (+) only in the S.G. columns. It must be pointed out, however, that of the six serums represented by the shaded area in the W.R. column, one only falls within the adjacent shaded area in the S.G. column, the remainder gave negative (four cases) or strongly positive (one case) S.G. reactions.

TABLE II.—*Comparative Results of Wassermann and Sachs-Georgi Reactions.*



A = One case only was doubtful to both reactions. Of the remaining five doubtful W.R.'s, four were negative S.G. and one strongly positive S.G.

Conclusions.

The results obtained from the formalin test prove once again the futility of basing conclusions on figures derived from a small number of cases, as small series have recently been published showing complete concord between formalin and W.R. results. The technique of the test is simple, and were the results reliable it would be an excellent method whereby the practitioner could rapidly establish a diagnosis of syphilis. But less than half of the serums giving positive W.R.'s shows coagulation with formalin, and—a fact of yet greater importance—nearly 10 per cent. of non-syphilitic serums give a positive result. Any claim to the reliability of the test is therefore demolished.

As regards the S.G. test the results obtained are distinctly promising. The technique is much simpler than that of the W.R. on account of the omission of the complement and other constituents of the hæmolytic system. But this is rather more than balanced by the great difficulty of determining the

FOUR GENITO URINARY CASES

ILLUSTRATING SOME DIFFICULTIES IN DIAGNOSIS

BY J. W GEARY GRANT, F R C S ENG ,
HON ASSISTANT SURGEON, KING EDWARD VII HOSPITAL CARDIFF

THE following cases well illustrate the difficulties of diagnosis in certain genito urinary conditions, and also the desirability in any obscure abdominal disease of a complete investigation of the genito urinary system X ray examinations, when negative, obviously only exclude such conditions as calculus, and when apparently positive still require verification of their findings by use of the cystoscope and ureteral catheter.

Tuberculous Kidney with Blocked Ureter

The case is remarkable in that he describes his pain as exactly the same as that which he had before the first operation, and refers it to the left side , nothing found at the second operation indicated that this was due to the gastric ulcer or his anastomosis He has never complained of any urinary symptoms

Accessory Renal Artery ? Intermittent Hydronephrosis

CASE 1 —A girl, aged 16, admitted to hospital March 30th, 1921, gave a history of a sudden attack of severe pain in the hypogastrium in February, with pain across the small of the back, coming on after micturition Extreme nocturnal and diurnal frequency and hæmaturia for 14 days Her own doctor diagnosed vesical calculus, and sent her to Dr Mitchell Stevens who diagnosed calculus in the left kidney or ureter On admission no pain, frequency, or hæmaturia a skiagram showed a shadow, the size of a shilling and very well defined, situated just to the outer side of and below the transverse process of the first lumbar vertebra (left) A second plate a week later showed the same as also one taken after her operation On cystoscopy the bladder and the ureteric orifices were normal, and urine came from each I, however, failed to get a catheter to enter the left On April 13th I exposed the left kidney and could find nothing resembling a stone in the kidney, pelvis, or ureter, or anything which corresponded to the shadow found in the plate There was, however, an accessory renal artery to the lower pole, passing behind the ureter at its junction with the pelvis of the kidney, and this I divided between ligatures Possibly this abnormal polar artery caused an intermittent hydronephrosis with hæmaturia Kidd and Ransohoff state that hæmaturia, often profuse, may follow temporary occlusion of the ureter in intermittent hydronephrosis and weighs 183 lb. His general outlook on life is much brighter, his disposition more cheerful and gregarious, and he has adopted his new life full of hope that his freedom from these distressing attacks may be permanent. The diagnosis is dermatitis herpetiformis.

20/9/21.—*The patient has now been free from his skin complaint for nine months.*

The chief points of interest in the case are these: (1) The early age of onset; (2) the intractable nature and increasing severity of the condition; (3) the absence of any nervous or other predisposing diathesis; (4) the precipitating action of sunlight and exercise; (5) the absence of eosinophilia; (6) the response to change of life from an outdoor to an indoor one, protection from the sun, and the administration of colloidal manganese; and (7) the mildness of the only attack which occurred during treatment.

It is hard to say how much of the improvement was due to the manganese, but this part of the treatment seems entitled to a considerable share of the credit. The change of living conditions interdicting severe exercise and exposure to the sun's rays is considered an important factor.

A NEW TREATMENT FOR

CHRONIC CERVICITIS AND ENDOMETRITIS.

By G. W. RUNDLE, L.R.C.P. & S. EDIN.,
HOUSE SURGEON, LONDON LOCK HOSPITAL FOR WOMEN.

WITH the exception of vesiculitis in the male there is no more difficult condition in medicine to treat than cervicitis and endometritis in the female. Though the lesions are primarily caused by the gonococcus, by the time the patients present themselves for treatment, in the great majority of cases, mixed organisms of a secondary nature only are found. In the cases subjected to treatment—they numbered 100—the gonococcus was found in 11 before treatment, and in none at its termination or later. These chronic vaginal discharges resist the orthodox treatments in a very persistent manner; consequently we experienced considerable satisfaction when we found that intramine pessaries stopped these discharges and at the same time healed erosions if present. The pessaries contain 1 per cent. of intramine (di-ortho-diamino-thio-benzene) in a stearine base. One is inserted per vaginam every night for about a month. In the test cases no other treatment was instituted, though we have found it advisable in a further series of cases—as it reduces the incidence of dermatitis—to prescribe a douche the following morning of a solution (1 in 1000) of either zinc sulphate or of zinc sulphanilate.

All the cases were treated as in-patients and kept under observation for some months afterwards as out-patients, being examined clinically and bacteriologically once a month. The oldest case is of 15 months' duration, and the youngest of four months' duration. An improvement in all cases was noticed at the end of the first week, when the patients invariably informed us that the discharge had stopped. Eight cases developed a local dermatitis, which immediately reappeared when the pessaries were prescribed again after an interval of a few months. Two cases relapsed clinically but not bacteriologically and cleared up again with another month's course. The dermatitis is due to the sulphur; it commences with itching of the vulva, and then the mucous membrane swells, a large quantity of lymph being exuded. The lesion may stop at this, or may spread to produce an erythema on the adductor region of the thighs. The inflammation rapidly subsides under calamine lotion. Intramine in the form of pessaries is quite painless, though in the form of suppositories it cannot be employed. That there is considerable absorption by the uterus of drugs inserted per vaginam is proved by the readiness with which the conjunctivæ become discoloured when picric-acid tampons are placed against the cervix for a few nights.

I wish to thank Mr. J. E. R. McDonagh for allowing me to publish these cases.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

WAR SECTION.

A MEETING of this section was held on Oct. 10th; Sir JOHN GOODWIN, Director-General A.M.S., was in the chair, and delivered his presidential address on

The Aftermath of War with Reference to the Medical Service of the Army,

in which he briefly reviewed some of the steps taken since the Armistice with regard to the Army Medical Service. On the cessation of active operations in 1918-19, he said, a necessary period of reconstruction in the army began. As regards the R.A.M.C., amongst the most pressing and self-evident desiderata were: the release of temporarily commissioned officers in order that the requirements of the civil population might be met; the closure of hospitals in order that expenditure might be reduced and that public buildings, &c., used as military hospitals might resume their normal functions; arrangements for the organisation of a satisfactory dental service for the army; a bringing up to date of all orders, regulations, war establishments, &c., so that these might be in accordance with modern requirements and with the lessons of the war; and the re-institution of classes of instruction for officers and men, schools of instruction having been closed at the outbreak of war, and the necessity of post-graduate and other education being now very evident.

Difficulties to be Overcome.

One of the difficulties in the way of attaining these ends was war weariness; after four and a half years of war everyone was tired, and many were almost worn out with incessant work, anxiety, and responsibility. Then, again, death and retirement had removed many able and distinguished officers. The urgent need for economy soon became evident; no measure which involved more than a minimal expenditure could be entertained. Moreover, an enormous expenditure of time and energy was required for the personal interviews, letters, &c., which had to be dealt with daily, the private and Parliamentary questions which had to be answered, and the criticisms—generally kindly, sometimes merely destructive and ill-informed—which had to be met.

Measures taken in Hand immediately after the Armistice.

At the time of the Armistice there were more than 364,000 military hospital beds in the United Kingdom alone; at present there were under 8000. An Army Dental Corps had been established and is doing excellent work. We had now more than 60 commissioned dental officers in the army, and a large number of other ranks employed as dental mechanics. Committees were formed to deal with the many questions relating to the amendment of existing regulations as to establishment, strengths of units, nature and scales of hospital equipment, stores, &c. The late Sir William Babtie, V.C., head of the chief committee, threw himself wholeheartedly into the work; on his death it was carried on by Major-General S. Guise Moores, and the labours of the committee were now completed.

The compilation of the official history of the war was begun under the editorship of Sir William Macpherson; the position as regards the Medical History of the War was as follows: The first volume of the General History, dealing with the medical services in the United Kingdom, garrisons overseas, and the Colonial expeditions, was now being bound for issue; the second volume, dealing with the medical services in France, would be complete early next year. The first volume of the "Diseases of the War" was almost ready for issue, cent. of glycerine was found to be the best quantity to add. On such media the spirochætes grew in small colonies, 1 to 2 mm. in diameter, with a dull rough surface and an irregular outline, and usually they were heaped up in the centre. The colour with young colonies was light fawn, but when older they became a rich brown. Secondary colonies usually appeared in old cultures. These were larger and smoother in appearance, but showed the same rich brown coloration.

The spirochæte stained with Giemsa's stain and by several of the silver methods, but showed no coloration with the ordinary aniline dyes. Growth took place under aerobic conditions, but none was observed in cultures placed anaerobically. Hanging-drop preparation when examined under the microscope revealed marked activity. The motion was swift and straight like a dart, a spirochæte often being scarcely visible until it commenced to slow down before reversing its corkscrew action and darting in the opposite direction. In stained film preparations the spirochætes were found to vary greatly in length, not only with the medium used, the degree of moisture, and the age of the culture, but also in the same film. The turns were fairly close, and varied from 1 to 30 or more in number. A flagellum was not observed, but no special attempts were made to demonstrate one. In older cultures, and particularly in the secondary colonies, the spirochæte forms gradually became much less numerous, and in their place was found a number of round bodies which varied in size from that of a large coccus to that of a small yeast cell. These forms contained a number of fine chromatin granules. Subcultures from these secondary colonies again grew typical spirochætes, but the growth at first was often small, indicating that many of the round forms were dead; it is possible that they represented degenerative changes. On the other hand, it is also possible that the round forms may need some further stimulus before they produce the original twisted forms.

Further cultivation experiments showed that no growth took place in ordinary peptone beef broth or on agar media. Negative results were also obtained in milk and on serum media. When inoculated into a flask of glycerine broth on which *B. phlei* was growing there was growth with turbidity. Growth also took place in glycerine beef broth on which an acclimatised Johne's bacillus was growing. In this case the masses of Johne's bacillus were broken up with the production of a marked alkaline reaction and a foul odour. After a short time, however, the spirochæte was acclimatised to grow—but with some difficulty—on an egg medium containing no *B. phlei*. No growth took place in broth media containing 10 per cent. of fresh sterile rabbit's blood, and after 24 hours' incubation at 37° C. the spirochæte was found to be dead. If, however, such media were previously incubated for 48 hours before inoculation, there was definite growth with hæmolysis. In such media the spirochæte grew exceedingly small, and was found to pass a Berkefeld filter, one drop of the filtrate giving a fair number of colonies on the surface of an egg medium containing *B. phlei*. Colonies, however, did not usually appear until after from three to five days' incubation.

Animal Experiments.

Small quantities of a culture were inoculated into the vein of a rabbit and pigeon and subcutaneously over the back of a mouse. The rabbit and pigeon gave negative results. The mouse at first showed no symptoms, but when observed seven weeks later it was found to be weak and to have developed several open sores on the back. The animal was killed. Films from the sores showed a large number of various micro-organisms, but no spirochætes could be found. In order to avoid the contaminations, cultures were taken from the deeper tissues beneath the sores. Contaminating bacteria, however, grew in large number, and the spirochæte was not recovered. No cultures were taken from the internal organs, as it was intended to inoculate other animals. Unfortunately, as I have pointed out, the work was interrupted by the war, and all my cultures died out. Since returning I have been unable to obtain any more infected mice, or any uncontaminated syphilitic material to test for the cultivation of *Treponema pallida*. Whether or no this micro-organism will grow on similar media or on similar media with slight modifications I am therefore unable to say. This, I suggest, should be tested, as should also the possibility of cultivating such organisms as that found by Noguchi in yellow fever. The possibility of using cultures like the one I have described for complement-deviation tests and immunity experiments should also be investigated.

In conclusion, I may mention that the spirochæte to be found in the stomach of normal cats and dogs failed to give the slightest evidence of growth on the special media, under either aerobic or under anaerobic conditions. Certain delicate vibrios and spirilla from soil and water, however, grew well on these media, and when dead *B. phlei* was added to a plain water-agar medium, it was easier to isolate some of these micro-organisms. The growth of certain amœbæ and flagellates was also good on such media.

I regret that circumstances should have made it impossible for me to complete this research, but I hope the results given here may prove of assistance to others workers in the same field.

THE ACCURACY OF THE FORMALIN AND SACHS-GEORGI TESTS FOR SYPHILIS

AS COMPARED WITH THE WASSERMANN REACTION

BY W. NEAVE KINGSBURY, B.Sc. LOND.,
M.R.C.S., L.R.C.P. LOND.,
ASSISTANT PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

(*From the Bland Sutton Institute of Pathology.*)

SINCE the discovery of the Wassermann reaction (W.R.), a number of tests have been put forward from time to time as substitutes, but few, if any, have withstood carefully controlled comparative tests against it. The following observations were undertaken in order to ascertain the diagnostic value of two of the more recent syphilis tests—namely, Gaté and Papacostas' formalin test and the Sachs-Georgi (S.G.) precipitation test. No attempt is made to discuss the theoretical aspects, the series having been carried out from the point of view of practical utility.

The Formalin Test.

The accidental discovery in 1920 by Gaté and Papacostas that the addition of a small quantity of formalin to pooled syphilitic serums produced coagulation and was without effect on normal serums forms the basis of this new test. In their original communication Gaté and Papacostas[1] state that two "drops" of formalin should be added to 1 c.cm. of syphilitic serum to produce coagulation. The indefinite volume of a "drop" necessitated a preliminary investigation to determine the optimum quantity of formalin to be employed. A pipette cut to No. 53 Stubbs wire gauge was used, and the addition of one drop of formalin, standardised to contain 30 per cent. of formaldehyde, to 0·25 c.cm. of serum, was found to give good results. A series of experiments was also carried out to confirm the optimum temperature for the reaction, room temperature being recommended by Gaté and Papacostas. Temperatures ranging from 0° C. to 56° C. were tried. It was found that if coagulation was complete at any one temperature, variation in temperature had little effect. If, however, the addition of formalin resulted in some slight increase in viscidity only, the change was perhaps slightly better marked at room temperature than at the extremes of the range. In view of these results room temperature

The **President** reported a similar case in whom the snap was produced by stimulating electrically during operation. He personally had not seen the monkey-like prolongation of the tendon of the gluteus maximus tendon described by Wood Jones.

Mr. **Elmslie** reported a case in which he had cured the hip-snapping as far as standing position was concerned, but the patient could now snap the hip when sitting.

Subluxation of the Hip.

Mr. **Fairbank** also showed a case of subluxation of the hip of doubtful origin. The case was first seen seven years ago, when she complained of a swelling of the hip and some pain, and limped on walking. There was slight limitation of abduction, but otherwise movements at the hip-joint were normal. A radiogram showed the head of the femur to be slightly flattened and displaced outwards on the neck of the femur. The upper part of the acetabulum was fluffy, with an ill-defined lip. The case was treated on a modified double Thomas hip-splint, with the legs in abduction. Owing to the war he lost sight of the case shortly after; but he saw her again in January of this year, when the swelling of the hip was more obvious and there was definite limitation of abduction. Trendelenburg's sign was now present, and there was ⅝ inch of shortening. A recent radiogram shows the neck of the femur shortened and definitely anteverted, and an enlarged and flattened head articulating with the upper lip of the acetabulum. The picture resembled that seen after reduction of a congenital dislocation, or more rarely that of a congenital subluxation, but he regarded the case as one of arthritis of unknown origin.

Sir **Henry Gauvain** said the case did not seem to him to suggest a tuberculous or inflammatory condition, and he was inclined to think the case was a congenital deformity.

Mr. T. H. **Openshaw** thought the condition was not congenital, as the head was too big. He considered it probable that it was a form of arthritis following an injury to the epiphysis, and thought no treatment would improve the condition.

The **President** agreed that the case was not congenital, and thought Mr. Openshaw's theory was probably correct.

Bilateral Absence of Radius.

Mr. G. R. **Girdlestone** showed a case of bilateral absence of the radius. When first seen both hands were in a position of right-angled radial deviation which he had treated by gradual extension of the contracted tissues by plaster. He discussed the question of a stabilising operation later on, and suggested splitting the lower end of the ulna and wedging the carpus into the gap or a lateral bone-graft to replace the absent lower end of the radius.

The **President** commented on the fact that absence of the radius was more common than absence of the ulna. He also inquired whether Mr. Girdlestone thought his lateral bone-graft would have any chance of surviving.

Mr. W. R. **Bristow** considered that periods of physical treatment by massage, &c., should be combined with periods of stretching by plaster, and thought that the question of operation depended on the amount of use which the child could make of the hands.

Mr. **Girdlestone**, in reply, agreed that alternate periods of fixation and massage were desirable. In reply to the President he said that he thought any graft operation would be successful where the graft had a definite function to perform.

Mr **Elmslie** showed a case of

Contracture due to a Burn,

causing great deformity and loss of function, cured by a plastic operation and illustrated the method which he had employed. The case was treated after operation by a cock-up splint and massage.

Paresis of Musculo-Spiral Nerve after Dislocation of Radius.

Mr. P. B. **Roth** showed a case of old dislocation of the head of the radius in a man of 38 years, causing paresis of the musculo-spiral nerve. When first seen the dislocation was of 20 years' standing, but the pain in the elbow of which he then complained was of only six months' duration. The pain was in the radial side of the hand, and getting worse. On examination the head of the radius was found dislocated forwards in such a manner as to lock against the lower end of the humerus and to prevent full flexion. A radiogram showed also curvature of the neck of the radius, making the head more prominent, and an old united fracture of the shaft of the ulna. A diagnosis of pressure on the radial nerve by the head of the radius was made, and for this condition he had removed the head of the radius. Nine and a half weeks after the operation the patient stated that all symptoms had disappeared and he has now resumed his work.

Mr. **Fairbank** thought that the head of the radius should not be removed from a young child. He had seen disastrous results follow such an operation.

Mr. **Elmslie** also reported a case in which the patient was extremely dissatisfied with the result of removing the head of the radius in an attempt to improve function.

Mr. **Roth** also showed a case of

Congenital Radio-ulnar Synostosis

after operation in a boy of 10 years. When first seen the left forearm was fixed in complete pronation so that the hand was practically useless. A radiogram showed a congenital synostosis of the upper ends of radius and ulna. An operation was performed during June of this year, and the bony union divided and the forearm put up in plaster in complete supination. After a few days the position had to be altered to one of mid-pronation on account of pain, and this position has been retained, although there was now very little movement of pronation or supination.

The **President** said he was unable to convince himself that any movement at the superior radio-ulnar joint was now possible.

Mr. **Fairbank** considered operation in these cases hopeless from the point of view of obtaining movement.

Mr. **Girdlestone** said that he had found it very difficult to retain movement in these cases, and he thought that if an arm which previously had been in a position of full pronation was put up in full supination after operation, a grave risk of ischæmia was incurred.

Mr. **Bristow** agreed with the President as regards the absence of movement, and suggested that any other cases operated on for this condition should be shown.

Mr. J. H. **Armistead** reported a case which had promised very well at first, but the bones had now fused together, and he could only regard the final result as a failure.

Mr. **Elmslie** suggested that the reason for failure in these cases was that the two most useful supinating muscles, the biceps and the supinator brevis, are both attached to the mass of bone which forms the synostosis.

Mr. **Girdlestone** had only seen one case where free excision of the upper part of the radius had resulted in a movable forearm, but in this case the forearm was flail, and the final result by no means an improvement on the original condition.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A **meeting** of this section of the Royal Society of Medicine was held on Oct. 6th, Prof. **Henry Briggs**, the President, being in the chair.

Exhibition of Specimens.

Dr. **Malcolm Donaldson** showed a specimen of Malignant Disease of the Cervix Uteri associated with a malignant omental cyst.

presence or absence of a precipitate in many instances A strongly positive S G reaction may be taken as evidence of syphilis, but a weak reaction must at present be looked upon with suspicion because of the difficulty in distinguishing between the weakest positive reaction and the slight precipitation given by some negative serums It appears possible, however, that the detection of the weakest positives may be made easier by modification of the antigen and by special methods of reading the results

The writer is indebted to Prof James McIntosh for many useful suggestions during these investigations

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

◆

A CASE OF
DERMATITIS HERPETIFORMIS

By A Keith Fraser, M D Aberd,

VISITING VENEREOLOGIST NEW SOMERSET HOSPITAL CAPE TOWN, LATE MEDICAL INSPECTOR OF VENEREAL DISEASES UNION GOVERNMENT OF SOUTH AFRICA

Dermatitis herpetiformis is a rare disease characterised by the chronic recurrence of papules, vesicles, or bullæ which may appear on any part of the skin, with a tendency to herpetic like grouping These are associated with intense itching and burning, which may be prodromal or concurrent This group of eruptions was originally described in England by Tilbury Fox under the name of hydroa, but it is generally known by the title which Duhring gave it in 1884 The cutaneous picture is very variable, and the multiformity of the eruptions considerable The blood picture shows a characteristic eosinophilia, and indicanuria is a frequent abnormality in the urine The course is intractable and treatment purely symptomatic, there is no specific remedy A case therefore, which responds to any line of treatment may be of assistance in determining the handling of these cases which are peculiarly persistent and recurrent

The patient was a South African male who had lived all his life in various parts of the Union His family history presented no points of interest He was not nervous as a child and he was healthy until the age of 11, suffering only from the usual zymotics At this age began the first of a long series of vesicular, papular, and bullous eruptions which continued for the next eight years without very much remission with increasing severity and at steadily decreasing intervals The earlier attacks were described as consisting of numerous clusters of small vesicles affecting chiefly the lower lip, the hands the inner aspects of the knees and the soles of the feet At first the interval between attacks varied from six weeks to three months, and the vesicles disappeared spontaneously in a few days As the boy grew older the interval between attacks steadily diminished, and the vesicle clusters persisted for longer periods There was also an appreciable prodromal period characterised by headache fever and general malaise The boy was something of an athlete playing games and running well in the short distances at school sports Such exercise invariably precipitated a severe attack which was worst on the soles of the feet When riding he always noticed that 'a crop of blisters appeared on the inner surfaces of both knees and thighs within a very short time

He led an open air life At the age of 17 he went to work on a farm and was out of doors all day in the heat of the African sun While he kept fairly fit in a general way these attacks steadily became more frequent, more severe, and of longer duration His general health and physical fitness were gradually undermined He had moved up country from the coast by stage and was now living at an altitude of some 1000 feet above the sea level He received all kinds of treatment during these years, but the effect on the incidence and severity of the attacks had been negative An autogenous vaccine had been made from the contents of the vesicles and he received many injections without effect. Meanwhile he had grown into a tall slimly built youth, naturally athletic, but severely handicapped by his condition As he grew older he noticed that the attacks caused him to feel miserable and off colour, and he indulged in sports with considerable trepidation The self consciousness caused by the unsightly appearance of the face went to increase a naturally retiring disposition, and the endless succession of eruptions became a real burden and obsession to the patient

At the age of 19 he came under my observation, and when I saw him first he had just had an attack in full swing He was ruddy in complexion and severely sun burnt, tall and lanky, of athletic build, and weighed 150 lb He was inclined to be constipated, and had a suspicion of pyorrhœa alveolaris He complained that all his endeavours to regulate his bowels were unavailing The following is his description of the onset of an attack When an attack is brewing I feel depressed, probably because I am aware of what is in store for me Small red spots appear which cause irritation Sometimes I think I feel feverish, but this may be imagination After a few days the red spots develop into blisters which grow larger and are fully developed about the third week While the blisters are growing they burn and itch with a throbbing sensation The places usually involved are exposed parts and the soles of the feet, on all scratches and cuts whether exposed or not, and on the lower lip and inside the mouth The upper lip is never attacked'

The lower lip was most seriously involved There were large vesicles about the size of a lentil interspersed with multiple smaller pea to pin head vesicles The lip itself was swollen and protruding and the surrounding inflammation intense There were numerous small vesicles on the buccal surface of the lip and cheek The vesicles remained discrete except at one point, where they had coalesced and formed a large multilocular bulla On the dorsal aspect of both hands and extending towards the wrists were several small clusters of small vesicles standing out on apparently healthy skin On the inner aspect of the left knee, however, the skin base was urticarial On the soles of the feet the skin seemed normal and the vesicles though clustered were discrete One or two large circinate bullæ of tough structure with considerable internal pressure were evident The contents of the vesicles were not autoinoculable Those on the soles of the feet were sterile but those elsewhere were contaminated by secondary organisms Considerable pustulation took place on the knee lesions and on the lip there was much eczematisation The urine was normal throughout, and the temperature did not rise at any time when under my observation The following is the differential blood count Polymorphonuclears 55 per cent, lymphocytes large 13 5 per cent, small 29 5 per cent = 43 per cent, mononuclears 0 5 per cent eosinophiles, 1 per cent, basophiles, 0 5 per cent The red cells were normal in colour, size and shape There was no eosinophilia

The attack subsided in three weeks time There was much scarring from previous eruptions on the thighs and knees The lower lip seemed indented and parchment like after the attack had passed off The patient was advised to give up his work on the farm for a time and if this had any influence on the frequency and severity of the attacks, to give it up entirely He was counselled to keep out of the sun as much as possible and wear a large brimmed sun helmet at all times Violent exercise was interdicted, but mild tennis was allowed in the cool evenings after a time These instructions were carried out most faithfully Diet was modified only to the extent of eliminating obviously indigestible foodstuffs

Further treatment consisted of weekly intramuscular doses of colloidal manganese The initial dose was 0 5 c cm and was very soon increased to 1 5 c cm There was no further attack for four months At this time on the occasion of a public holiday the patient sought permission to go riding on a picnic excursion This was given after warning him of the risks of precipitating an attack He was anxious however, to try how much risk he might run with impunity On this occasion he was out in the broiling sun for 12 hours Most of the time he was riding a restive horse After sundown he played tennis and subsequently went to a dance where he performed vigorously for many hours Within four days one or two tiny vesicles appeared on the lower lip, and also on the soles of both feet They did not develop, however and had disappeared completely in a few days The prodromal itching and burning were very slight

With this sole exception there has been no further attack within eight months of leaving the farm and taking weekly injections of manganese The patient s health has improved out of all recognition and he is no longer inclined to be constipated He has grown and put on weight in the most astonishing manner He now stands 5 ft 10 in chronically inflamed decidua often left behind by the placenta were favourable beds for the development of septic organisms. Polypoid decidual endometritis was neither a hypertrophic nor an adenomatous condition as was formerly taught, but was a combination of chronic endometritis and metritis exaggerated by pregnancy and usually showing the signs of acute inflammation grafted upon the old chronic condition as the result of sepsis in the puerperium. Syphilis was one cause of the condition and possibly chronic gonorrhœal infection might be another.

Dr. Nyulasy urged practitioners to submit for microscopic examination the material removed as retained products of conception after labour or miscarriage, as polypoid decidual endometritis would, in his opinion, be found to be of much more frequent occurrence than was suspected. As to symptoms, the patient might appear to be doing well for a day or so. but usually there was a slight rise of pulse, then of temperature, which might rise to 103° or 104° F. on the third day. There might be free bleeding after labour, but profuse secondary hæmorrhage was not common, though a sudden free flow after the passage of a normal amount for two or three days was suggestive. Diagnosis depended on the presence of subinvolution, a patulous os usually admitting two fingers, and in the uterus a mass of varying size usually covered with blood-clot, together with the symptoms described. Prognosis depended on the virulence and dosage of the infecting organisms and the tissue-resistance of the patient, but chiefly on the promptitude and efficiency of the removal of the polypoid masses after labour or miscarriage. Practically every case recovered if the operation was done early, but if this were delayed the danger was extreme. As to treatment, early and complete removal of the infected polypoid masses was essential, and from the third to the fifth day was the best time for interference. The major part should be removed by the fingers, but the remainder, which might extend right down to the external os, might be cleaned off with a large-looped sharp curette. Dr. Nyulasy said that the fingers alone might be used if the operation could be performed satisfactorily by this means.

Dr. AMAND ROUTH said he had been struck by a description of Virchow's specimen in a book which he reviewed 30 years ago. He was surprised that more had not been heard of this important condition, and he complimented Dr. Nyulasy on the care with which he had prepared his material for this paper.—Dr. A. E. GILES pointed out the importance of the condition from the medico-legal point of view. It had been a natural but in many cases evidently an unfounded assumption that portions of tissue of polypoid form removed after delivery were placental in character, and were, therefore, to be considered as having been overlooked. It would now appear that in justice to the attending practitioner such tissue must be microscoped before a dogmatic opinion was expressed.—Dr. J. S. FAIRBAIRN thought that many of the figures and sections demonstrated by Dr. Nyulasy showed merely necrotic decidua, and thought that more proof would have to be adduced before the condition could be labelled as syphilitic.—Dr. BARRIS said that he also had felt masses in the decidual site, but he could not feel satisfied that they were polypoid decidual masses. He wished to protest against the use of the curette so soon after labour.—The PRESIDENT inquired whether those septic cases which did well with intra-uterine douching were to be considered as polypoid decidual endometritis. He also felt that curettage was dangerous within 12-14 days after delivery.

Dr. NYULASY, in reply, said he thought that the condition began at or before conception. As regards removing the polypoid masses, he usually employed his fingers, but sometimes had been compelled to use a curette on account of the large area of endometrium involved. He then employed a sharp curette as he thought this caused less trauma. He thought that 3-5 per cent. of all pregnant uteri exhibited the condition, but he could not say what proportion of septic cases were due to polypoid decidual endometritis.

Reviews and Notices of Books.

SANITARY LAW AND PRACTICE.

A Handbook on Public Health. Fifth edition. By W. ROBERTSON, M.D., Deputy M.O.H., Edinburgh; and CHARLES PORTER, M.D., M.O.H., Metropolitan Borough of St. Marylebone. London: Sanitary Publishing Co., Ltd. 1921. Pp. 758. 18*s.* 6*d.*

A BOOK on the subject of sanitary law requires frequent revision to keep it abreast of the times, owing to the passing of new enactments and the issue of fresh regulations and circulars by the Central Health Authority. There is little change in the general plan of the fifth edition of Robertson and Porter's handbook, which first appeared in 1904. The various Acts and laws relating to public health in England and Wales, Scotland and Ireland, are condensed and conveniently arranged under different headings to facilitate study. But the book is more than a guide to the Public Health Acts, because not merely are the laws and regulations explained, but practical suggestions on the usual methods of administration appropriate to each branch of the subject are given. This is of great advantage to the student, as the working aspect of sanitary administration is rather neglected in most text-books on public health. In the present edition we cannot find any reference to the Port Sanitary Authorities (Infectious Diseases) Regulations, 1920, and are surprised that regulations of such importance to *port sanitary authorities and their officials* in connexion with the prevention of the introduction into this country of infectious diseases from abroad should have been omitted.

Certain of the statements made on the subject of vaccination call for comment. The authors express the view that, so far as their experience goes, vaccination is not being efficiently carried out, and add:—

> "It is only necessary to examine the arms of children to become convinced of this fact. It is rare to find more than *two marks in any case, and very commonly only one mark* can be found. Very commonly, also, instead of finding foveated marks nothing but cicatrices are to be seen. It is not common that any individual mark is of an area of half an inch square, as recommended by the Royal Commission on Vaccination."

Possibly the authors' experience of vaccination relates. for the most part, to conditions found in Scotland, where "one mark vaccination" is still commonly practised. Public vaccination in England and Wales is, of course, performed by public vaccinators appointed by the boards of guardians. Their work, which is carried on in accordance with instructions issued by the Ministry of Health and under the supervision of the Central Health Authority, generally attains to a high standard of efficiency. The public vaccinators are instructed to aim at producing four vesicles or groups of vesicles having a total area of half a square inch on the eighth day after the operation has been performed. We are not aware that the Royal Commission on Vaccination recommended that each individual mark should be of an area of half an inch square, though they did state on p. 99 of their final report that:—

> "We think it may fairly be concluded that where the vaccine matter is inserted in three or four places it is more effectual than when introduced into one or two places only; and that if the vaccination marks are of an area of half a square inch, they indicate a better state of protection than if their area be at all considerably below this."

It will be noted that the Royal Commission suggest that the three or four vaccination marks taken together should be of an area of half a square inch. It should also be noted that there is considerable difference in the *meaning of the terms* "half a square inch" (used by the Commission) and "half an inch square" (employed by the authors of this book).

and the first volume of the "Surgery of the War" was complete in galley proof, and the second volumes of both these works were only awaiting a few chapters; the "Surgery" was practically complete. The material for the volumes on the hygiene of the war would be prepared for press by Sir William Horrocks early next year. The volume on pathology was not, so far as the material in the office is concerned, very far advanced, but ten of the subjects had been written up, and the MS. was in the office. There was no indication as yet with regard to the volume on statistics, and it is doubtful whether complete statistics would eventually be obtained for all periods of the war and for each area of operations.

R.A.M.C. Training.

It was felt that officers stationed in the provinces had frequently not the facilities for obtaining clinical experience afforded to those who were near London; the large provincial hospitals and infirmaries were therefore approached in the matter with very satisfactory results. Over one hundred officers had since the war passed through the post-graduate classes at the R.A.M.C. College, Millbank; 59 officers passed as "distinguished" in various subjects. It was hoped that all these officers may in the future obtain appointments as specialists in the subjects in which they have specialised. In addition, several officers presented themselves for examination in higher degrees, with good results. An important recent concession had been the grant of an initial sum of £220, with a subsequent annual grant of £150, for the purpose of establishing professional libraries in all our larger hospitals in order that officers might have at hand the most recent works for reference. Helped by this grant every military hospital at home and abroad might have an adequate and up-to-date library. Directorates in Hygiene and Pathology were established in 1918 under Colonel W. W. O. Beveridge and Major-General Sir William Leishman. The work carried out by these directorates was of untold value to the army. The posts of consultant in medicine and consultant in surgery had now been established; these appointments would—as in the case of the directorates just mentioned—normally be held by officers of the rank of full colonel. Should a more junior officer be appointed he would hold the temporary rank of full colonel with the pay and allowances of that rank. With regard to all these appointments—viz., Directors of Hygiene and Pathology and Consultants in Medicine and Surgery—one very important point was that should any officer holding one of these appointments come up in due course for promotion to the rank of major-general, he might be so promoted as supernumerary to the establishment of major-generals and continue to hold his appointment. Consequently the rank of major-general was now open to officers who specialised in pathology, hygiene, medicine, or surgery.

R.A.M.C. War Museum.

The R.A.M.C. War Museum had been the subject of an immense amount of discussion and correspondence, which had at last resulted in a really satisfactory solution. The Treasury had given a sum of £7500 to the Royal College of Surgeons of England, and that body had generously agreed, for this sum, to house, maintain, care for, and complete the preparation of the entire pathological collection of war specimens, and also certain selected facial and orthopædic exhibits.

SECTION OF SURGERY: SUB-SECTION OF ORTHOPÆDICS.

A MEETING of this section of the Royal Society of Medicine was held on Oct. 4th, Mr. E. LAMING EVANS, the President, being in the chair.

Fibrous Osteitis.

Mr. W. H. OGILVIE showed a case in which subperiosteal resection of the humerus had been performed for fibrous osteitis. The patient, a boy aged 3½ years, had been an in-patient in Guy's Hospital during March, 1921, on account of an increasing swelling of the right upper arm of six months' duration, causing no pain or disability beyond slight limitation of voluntary abduction at the shoulder. A skiagram showed a cystic expansion of the bone indicative of myeloma or simple cyst. At the first operation the swelling was exposed subperiosteally and a portion of the outer bony wall removed. The interior contained a reddish material and bled freely. It was thoroughly scraped out, and the cavity swabbed with perchloride of mercury solution. The pathologist's report was that the material formed part of a fibrous osteitis with numerous giant cells resembling those of a myeloma. After the operation the swelling of the arm continued, and three months afterwards an X ray report stated that the cystic expansion had increased both vertically and in circumference, although attempts to fill the cavity with new bone were observed. A second operation was performed on June 23rd, 1921. The whole length of the humerus was exposed and 6½ inches of the bone resected subperiosteally. This included the whole cystic area, and was found on examination to contain a small portion of the upper epiphyseal cartilage. It had been intended to replace this by a bone-graft from the tibia, but the patient's condition did not permit of this, and he was returned to the ward after the periosteum and skin had been sutured. The boy developed broncho-pneumonia, and no treatment of the arm was possible for ten days. On the sixteenth day, when the arm was examined, it was found to be firm on its whole length, and a skiagram taken two days later showed a definite shadow occupying the whole gap. The arm was then placed in a position of right-angled abduction and massage given. At the end of six weeks the bone had regenerated with half an inch of shortening and a full range of movement in both the shoulder and elbow, except for slight limitation of extension at the latter, due to scar, which is now keloid. Mr. Ogilvie, in demonstrating the case, discussed the pathology of the condition with regard to its intermediate position between a simple granuloma and a myeloma. He personally called the case one of fibrous osteitis.

Mr. R. C. ELMSLIE said he had seen three similar cases cured by curetting, and preferred the term fibro-cystic disease since it did not imply a new growth. He considered that bone-grafts in these cases merely acted mechanically as a means of keeping the bone straight whilst regeneration took place.

Mr. H. LAWSON described a similar case, which he had observed for some time. The condition was not causing any disability and was apparently not progressing. He asked the advice of members as to whether operative treatment should be advised.

Mr. W. T. G. PUGH advised radium treatment for the keloid, and stated he had found it successful in a similar case.

The PRESIDENT remarked that this case illustrated well why bone-grafts in children were so successful.

Bilateral "Snapping" Hip.

Mr. H. A. T. FAIRBANK showed a case of bilateral "snapping" hip in a child, being a further report in a case already shown. On the former occasion the President in commenting on the case said he had cured a similar case by rest in plaster. The worse hip, the right, was operated on in December last, when the tendinous formation described by Wood Jones was observed on the deep aspect of the gluteus maximus, although it was not well developed. A flap of periosteum was turned forward from the posterior aspect of the great trochanter and this tendon stitched beneath it. By this proceeding the femoral attachment of the muscle was prolonged upwards to the top of the trochanter; the other hip was put in plaster in slight abduction. When seen in July last the patient had had no recurrence of the snap in either hip.

operations there follows as a rule some wise advice as to choice of method. In this edition the many recent advances in thoracic, abdominal, and plastic surgery have been incorporated. In the section dealing with plastic operations on the nose the author has not sufficiently emphasised the importance of putting an epithelial lining to any flap used to remake the nose. Unless this is attended to a shrunken and unsightly nose results. It is surprising that the name of Lotheissen is not mentioned in connexion with inguinal operation for femoral hernia. In the section dealing with hepatic abscess the author does not seem to have adapted the technique in accordance with more modern views. Even in a book on operative surgery it would be wise to point out that most liver abscesses are due to the *Entamœba histolytica*, whose destruction is assured by treatment with emetine. Moreover, the pus in such an abscess is aseptic, and to pack the cavity with iodoform gauze is totally unnecessary. The less the cavity is meddled with the better, so long as room for the exit of the debris is assured. Aspiration of a liver abscess, when accompanied by the employment of emetine, is a successful method which should receive recognition. The section dealing with subphrenic abscess is inadequate for a book of this size. To give 20 pages to rhinoplasty and six lines to subphrenic abscess is surely to show a lack of proportion. The many types of subphrenic abscess are approached by different routes which should be specified. Room could easily be made for this by cutting out a few of the rarer operations.

However, in spite of minor deficiencies the Manual is indispensable to every practising surgeon.

EARLY DIAGNOSIS OF THE ACUTE ABDOMEN.

By Zachary Cope, B.A., M.D., M.S. Lond., F.R.C.S. Eng., Surgeon to Out-patients, St. Mary's Hospital, Paddington. London: Henry Frowde and Hodder and Stoughton. 1921. Pp. 223. 12*s.* 6*d.*

All surgeons have realised the difficulty in diagnosis associated with acute emergencies within the abdomen. In this little book Mr. Cope deplores the growing tendency to shirk the issue after the preliminary recognition of an acute condition, and to leave the actual lesion to be discovered at operation. No apology is needed for the repetition and emphasis of the axiom that correct diagnosis is an essential preliminary to correct treatment, or that neglect to make a careful and exhaustive examination is the factor most likely to cause unnecessary delay in operative treatment. More things are missed by not looking than by not knowing, and the memory of this teaching has spurred many a weary practitioner to a fruitful search in apparently unlikely directions. Mr. Cope gives a good description of the methods of investigation that should be employed with every variety of acute abdominal condition and the help afforded by accurate differentiation of types of pain and vomiting is carefully explained. The section on the examination of the patient is none the worse for the fact that there are one or two points on which other surgeons may not agree with Mr. Cope. In testing hyperæsthesia of the skin most neurologists believe that pinching a fold of the skin elicits not true superficial tenderness but deep sensibility. This difference of method may account for the fact that the areas of superficial tenderness here suggested for certain diseases are not in accordance with those usually found. For instance, the area of superficial tenderness described by Mr. Cope as diagnostic of a distended appendix is placed just to the right of the umbilicus; whereas the researches of Head and Sherren have located it over the right Poupart's ligament: most surgeons would agree that true superficial tenderness as elicited by a dragged pin is so situated, the presence of this sign being strong evidence of a distended appendix, for it disappears as soon as the appendix perforates. Mr. Cope's own experience as a surgeon has led him into some unfrequented regions, and he draws the reader's attention to a number of diagnostic points apt to be missed by those who do not look for them, for example, the right shoulder pain suggestive of a diaphragmatic lesion, and the test, described as the obturator test, which is a useful sign in a pelvic infection. Although the tabular arrangement makes the book very convenient for purposes of revision, the volume should prove extremely useful to general practitioners and to those holding appointments which entail the treatment of abdominal emergencies.

PATHOLOGICAL HEREDITY.

Einführung in die Allgemeine Konstitutions- und Vererbungspathologie. By Dr. H. W. Siemens. Berlin: Julius Springer. 1921. Pp. 229.

The author begins by stating, truly enough, that the subject of pathological predisposition and heredity has a muddled terminology and no text-book. In fulfilment of a purpose thus indicated, he sets out to "assemble" the relevant information, and in so doing shows much knowledge and general culture. The chief stress is naturally laid upon Mendelism, since that is the most exact instrument the investigator in this field can wield. Whether it can be used with advantage, at any rate as yet, may be doubted. On low forms of life, and on rare, highly particularised human diseases, Mendelism may throw light. But, as the biometricians have not been slow, or loth, to demonstrate, in more complicated phenomena little in the way of unit behaviour is discernible. Dr. Siemens might have done better to have dwelt more on metamorphic pathological heredity—the *hérédité dissemblable* of the French—and better still to have accumulated figures (perhaps he is so doing), not necessarily for mathematical treatment, but so as to secure ordinary exactness. There are 80 illustrations in the book, and workers from all countries are mentioned.

TEXT-BOOK OF NURSING PROCEDURES.

First edition. By Anna C. Jamme, R.N., Director of Bureau of Registration of Nurses, California. New York: Macmillan Company. 1921. Pp. 140. 7*s.* 6*d.*

To those student-nurses who find help from illustrations, Miss Jamme's book on Nursing Procedures may serve to assist in the co-relation of the theory and practice of nursing. The book cannot be considered a substantial contribution to nursing literature, consisting as it does only of a collection of illustrations of nursing procedure which may be found in all good general text-books. As a supplement, however, to a text-book deficient in illustrations, the little volume may be of use.

THE MICROTOMIST'S VADE-MECUM.

A Handbook of the Methods of Microscopic Anatomy. Eighth edition. By Arthur Bolles Lee, Hon. F.R.M.S. Edited by J. Brontë Gatenby, B.A., D.Phil., D.Sc., F.R.M.S. London: J. and A. Churchill. 1921. Pp. 594. 28*s.*

It frequently happens that a scientific text-book, after a few years of deserved popularity, falls gradually into oblivion. It becomes out of date, and its author, dreading the drudgery of bringing out fresh editions, is content to see it die. True, the task of revision may be undertaken by another, but too often the result is mediocre; there is lacking the touch of the vanished hand. The eighth edition of Lee's Microtomists' Vade-mecum is a distinguished exception to this dreary rule. Under the capable editorship of Dr. J. Brontë Gatenby it is revitalised, and once again becomes the best text-book on this subject in the English language. While the general character of the book remains unaltered, it has been carefully revised, and the addition of fresh sections, all happily conceived in the spirit of the original, brings it thoroughly up to date.

Dr. Gatenby himself, in addition to undertaking the general revision, has written on many subjects including chromatin and chromosomes, mitochondria, The PRESIDENT showed a specimen of Green Intraperitoneal Exudate found covering the middle third of the back of the uterus during the operation of Cæsarean hysterectomy, performed for obstructed labour with signs of failure of the fœtal heart. The patient had a fibroid which had been symptomless and undiscovered until the fifth month of pregnancy when one day's acute abdominal pain occurred without fever or vomiting. The pain gradually subsided, and she was in bed for three weeks. Prof. Briggs thought it an open question whether this pain did or did not correspond to the early stages of the exudate. The exudate resisted complete detachment; its texture was organically cohesive; its organisation was feeble, and its thickness was a quarter of an inch. Prof. W. Ramsden of the biochemical department had reported the absence of bile pigment and the presence of hæmoglobin or hæmatin; he had since remarked that alkaline hæmatin when diluted acquires a green colour. Dr. R. A. Hendry had examined the specimen and described an organising blood clot with a shell of lutein tissue and granules of pigment, indicating a condition of some long standing, and Prof. Ernest Glynn agreed with Dr. Hendry. Prof. Briggs said that the child was asphyxiated and collapsed at birth but recovered, and the health of both mother and child is now good.

Large Hæmatoma of the Vulva following Labour.

Dr. H. J. MCCURRICH then read a paper by Dr. J. D. BARRIS and himself on a case of Hæmatoma of the Vulva following Labour. The case was reported on account of the unusual size of the hæmatoma.

The patient, a married woman, aged 35 years, had already borne three children without complications. Labour occurred before admission to hospital. The doctor who attended her stated that the fœtal head was on the perineum when he arrived; forceps were not used, the perineum was not torn, and the placenta came away shortly after without abnormal hæmorrhage. One and a half hours afterwards the patient experienced great pain between the thighs and bled slightly. Her doctor was summoned and found a large hæmatoma of the vulva. Later in the day the pain was so severe that he gave her an injection of morphia and sent her to St. Bartholomew's Hospital. On admission at 8 P.M. the patient was blanched, temperature 97·4° F., pulse 96. The left labia, majus and minus, and the left half of the perineum were markedly distended by a purple shiny oval swelling, the left labium minus being stretched over the centre of the swelling as an œdematous band. The swelling was 9 in. by 4½ in., tensely elastic, but not markedly tender. There was slight blood-stained oozing from the vagina, but the surface of the swelling appeared intact. Under gas and oxygen anæsthesia an incision 1½ in. long was made just internal to the labium minus, and 18 oz. of blood clot were evacuated. No bleeding-points were found. The cavity was irrigated with hot saline and lightly packed with gauze. Prophylactic doses of sensitised streptococcal vaccine were given, and the patient made an uninterrupted recovery, being able to nurse the child. Three months later the patient came up and reported that the scar had not caused dyspareunia or any other inconvenience.

Dr. CLIFFORD WHITE said he had seen a similar case, but in that instance the hæmorrhage began 30 hours after labour. This case was also treated successfully by incision, packing, and pressure.—Dr. A. LAPTHORN SMITH said that he had recently attended a case in which a varicose vein of the vulva ruptured giving rise to severe external hæmorrhage.

Dr. R. A. HENDRY read a paper on

A Case of Prolonged Gestation.

He said that the interest in cases of post maturity aroused by a recent law suit[1] was his reason for reporting the case. The patient had had four children, the last 18 years ago, and three abortions. Her husband went to Australia in 1913, and returned to Liverpool, his native city, four years later as a sergeant in the Australian Forces. He spent the night May 14th to 15th, 1917, at home and then returned to his unit. Six months later the patient came to the clinic and was found to be six months pregnant. She was again examined Dec. 18th, 1917, when the uterus was the size of a seven months pregnancy. She attended the clinic again on March 19th, 1918, a month overdue, and was not delivered until April 8th, 1918—328 days after coitus, and 361 after the last menstruation. The midwife informed Dr. Hendry that labour was normal; there was no excess of liquor amnii and the baby was of normal size—it weighed 7 lb. 14 oz. on seventeenth day when it first came to a welfare centre.

Criticism in Dr. Hendry's view might lie in various directions: (1) errors in observations; (2) causes of discrepancy between the size of uterus and the gestation history; (3) lack of corroboration of observation. On the first count a 280-day gestation terminating on April 8th, 1918, would have begun on July 2nd, 1917. Nov. 20th would be 20 weeks later and Dec. 18th 24 weeks; so that on this supposition a 20 weeks uterus must have been taken for a 27, and a month later a 24 weeks uterus for a 31. A double error of such magnitude was, he thought, unlikely. On the second count, hydramnios and twins might be excluded, and no suggestion of a fibroid was ever found. The third possible source of error, lack of corroboration, was practically inevitable in the circumstances.

The PRESIDENT thought that oversize would not account for most cases of prolonged gestation.—Dr. HENDRY said he had noticed in some cases a corelation between prolonged gestation and oversize.

Dr. FRANK NYULASY (Melbourne) read a paper on

Polypoid Decidual Endometritis,

illustrated by epidiascopic and microscopic illustrations and naked-eye specimens. Dr. Nyulasy said that it was a disheartening and almost humiliating discovery to find by the Registrar-General's report that puerperal mortality in England and Wales was greater in 1919 than in any year since 1908. One important cause of puerperal septic infection appeared to be quite generally overlooked—polypoid decidual endometritis. This disease was first mentioned by Virchow in 1861 under the name of "endometritis decidualis polyposa vel tuberosa." Since Virchow's time Gusseron, Strassman, and others had recorded odd cases associated with abortions, but the condition had been generally regarded as a pathological curiosity of extreme rarity. Dr. Nyulasy contended from his own observations that the disease was not uncommon though often unrecognised; that it was associated with full-time labours and not only with abortions, as hitherto recorded; and that it is a not uncommon cause of septic infection with its resulting consequences. In cases occurring in full-time pregnancy the placenta, or a portion thereof, might be found adherent to the diseased decidua; but on the other hand, it might come away apparently complete, leaving behind masses of polypoid decidua which might undergo septic infection, and if not promptly removed lead to the death of the patient. Polypoid decidual endometritis was a result of pre-existing chronic endometritis beginning prior to, or coincidently with, pregnancy, and continued into the puerperium, during which acute processes were grafted upon the old chronic condition in consequence of septic infection. Evidence of chronicity was shown by the fact that in many cases the condition was found to be syphilitic in nature, as evidenced by the history and the microscopic findings. An extreme degree of endarteritis obliterans, which was essentially a chronic process, was always found in such cases. With it there was often considerable organisation of the immense thrombosed capillaries and new formations of fibrous and muscular elements. The flattened, elongated, venous spaces were mostly empty except for a few blood corpuscles, and were lined with a single layer of endothelium in places undergoing active proliferation. Decidual cells, rounded, oval, polygonal or flattened, were found in some specimens over fairly large areas, often separated by bands of muscular and fibrous tissue or forming "decidual islands." Signs of recent inflammatory reaction were chiefly shown by small round-celled infiltration, small extravasations of blood, and active endothelial proliferation. In some sections a few villi were found attached to the polypoid tissues. The masses of

[1] THE LANCET, August 13th, p. 357.

Stegomyia larvæ:—(1) a new ciliate: *Lambornella stegomyiæ* n.g., n.sp.: (2) a new type of a fungus: *Cœlomomyces stegomyiæ* n.g., n.sp. The host, *Stegomyia scutellaris*, is known as a carrier of malaria and filariasis.—The number concludes with a monograph, by Makoto Koidzumi, on the Intestinal Protozoa found in the Termites of Japan. This paper contains detailed cytological and systematic studies of the trichonymphides.—Portraits of Karl Asmund Rudolphi (1777–1832), Johannes Müller (1801–1858), and Joseph Leidy (1823–1891) are included with this number.

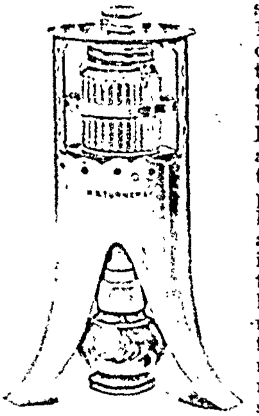
AMERICAN JOURNAL OF OPHTHALMOLOGY. August and September, 1921.—A case of typical siderosis of *crystalline lens, with no clinical evidence of a splinter* of iron, described by D. van Duyse (Ghent) and Mr. Danis (Brussels) in the August number, is of some interest from a medico-legal standpoint. Two years after the receipt of a wound in the eye from a casting thrown off in cutting a pipe, the crystalline lens was found to be so opaque that vision was reduced to counting fingers at 1·5 meters. In the substance of the lens were nine rust-coloured spots with diffused margins, but no foreign body could be discovered either by X rays or by the magnet. The authors believe that a small metallic particle is nevertheless present, probably fixed between the fibres of the lens. The appearance of the siderosis spots is illustrated by a coloured plate. Other articles in this number include one by E. Maddox, giving details of some new subjective tests for the detection of the true axis in astigmatism; one by H. K. Fleck on disciform keratitis secondary to smallpox; and two articles on ocular manifestations in encephalitis lethargica, by P. J. Waardenberg and G. I. Hogue.

To the September number Burton Chance contributes *an article on radium plugs for the dissolution* of orbital gliomatous masses developing after excision of the globe. In the case recorded the mass filled the orbit, pushing the lids forward. Nine plugs or "needles" containing radium were inserted deeply into the mass and allowed to remain for 20 hours. An erythema of the lids lasted a number of days, and the lids themselves were puffed with a more or less ichorous discharge. *Four months later the mass* appeared to have been completely dissolved. The success is attributed to the method of employing the radium. In the same number Walter R. Parker has tabulated the results of his cataract operations by different methods, and Dimitry in a paper on hereditary ptosis includes a family tree proving its persistence through five generations and showing the method of inheritance of a Mendelian dominant. Out of 38 individuals 21 showed the peculiarity. It was transmitted equally through males and females, but never by one who was normal. Strictly speaking, the condition was not a true ptosis but a blepharophimosis or small palpebral aperture stretched horizontally, a condition for which the ordinary operations for ptosis would be unavailing.

New Inventions.

A HOT-AIR STERILIZER FOR STEEL NEEDLES.

THE *sterilizer here illustrated constitutes an attempt* to solve the usual troubles experienced with steel needles and also to afford painless injections. The apparatus consists of a tripod, nickel-plated steel sterilizer 8·5 in. high with an upper chamber 3 in. by 2·75 in. In the upper chamber is a carrier supporting a bottle of 40 needles held up by their hilts in open glass tubes, the points being free. The bottle is one-third filled with fresh liquid paraffin. Heat is supplied by a spirit lamp below, and sterilization occurs in 12 to 15 minutes. This is indicated by a gentle tinkling of the boiling paraffin, which takes place at 118° C. The bottle is then removed by a lifter. An Arkansas stone and a neat leather case containing also a bottle of liquid paraffin and a spare needle bottle are supplied optionally. The apparatus is intended for the conservation of steel needles in hospitals, in the consulting-room, and also especially for V.D. clinics, where a number of fresh sterile needles are required in series. Re-sterilization of the bottle when once opened is not necessary if due asepsis in extracting needles is observed. Far greater comfort to the patient can be attained by sharp, unoccluded and properly lubricated needles which have not rusted than by the conventional needle preserved in spirit. The sterilizer prolongs the life of steel needles very materially.



The wholesale makers are Messrs. R. B. Turner and Son, 9-11, Eagle-street, Southampton Row, London, W.C., to whom I am indebted for assistance in working out the details.

Eastbourne. A. G. SHERA, M.D. Cantab.

AN ADJUSTABLE JOINT FOR GERM-PROOF FILTER CYLINDERS.

THE London Filter and Pump Company has introduced a new form of joint and nipple for filter candles. The object is to eliminate entirely the risk of fracture of the candle, an accident to which the fixed mounted cylinders are liable during sterilisation by heat. When this defect occurs, it does so at the junction of the metal cap and the cylinder, owing to the great difference between their coefficients of expansion. The construction of the nipple and joint is shown in the illustration.

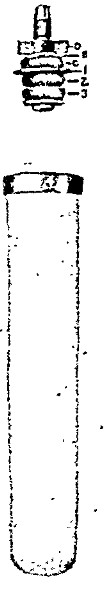


FIG. 1.—1, metal disc. 2 and 3, washers. 4, metal cap of cylinder. D, fly nut.

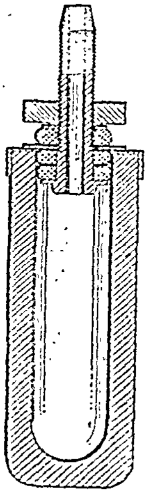

FIG. 2.—Section of nipple, joint, and cylinder.

The method of adjusting the joint is extremely simple. The nipple is pushed into the filter cylinder until the large metal disc rests on the cap of the cylinder. The fly nut is now screwed up tightly, thereby compressing the indiarubber washers and causing them to expand laterally on to the inner surface of the cylinder. By this action an *impervious joint is* formed. The metal cap, which is fixed round the top of the cylinder, effectually prevents fracture from the outward thrust of the indiarubber washers. A cylinder fitted with this form of nipple has given sterile filtrates over a considerable period. For the purpose of cleaning both surfaces of the cylinder and autoclaving at 120°C., the joint has to be disconnected. This has been done many times, over a period of three months with one specimen, without the joint losing its efficiency.

The advantages of such a filter cylinder will be appreciated by all bacteriological and public health authorities. E. T. THOMPSON.

Ministry of Pensions Hospital, Orpington, Kent.

PSYCHO ANALYSIS AND THE WAR NEUROSES

By DRS S FERENCZI, KARL ABRAHAM ERNST SIMMEL and ERNEST JONES London George Allen and Unwin, Ltd 1921 Pp 60 7s 6d

THE psychological study of the war neuroses in this country has established certain of the claims made by psycho analysts the unconscious motive and the processes of repression and of symbolisation by symptoms were found constantly to occur, and treatment by reviving the memory of forgotten incidents (the "cathartic method of Breuer and Freud) was found to remove the associated symptoms These successful results are, however, regarded some times as disproving the fuller Freudian theory, especially the principle that the primary repressed wish ultimately responsible for the neurosis is always of a sexual nature Writers on the war neuroses accept psycho analytical views in varying degree, but psycho analysts themselves have written very little on the war neuroses Dr Ernest Jones suggests the cause when he says that he has made an intensive study of only some half a dozen cases (this was in 1918), and does not know of any others that have been investigated by the psycho analytical method

"Psycho analysis and the War Neuroses" gives the views of leading psycho analysts as expressed at a congress at Budapest, and in a paper by Dr Ernest Jones which was read at the Royal Society of Medicine In a short introduction Freud admits the difficulty of bringing the traumatic neuroses into his ætiological conception but declares that if war neuroses have not shown the sex theory to be correct, yet that is quite another matter from showing that it is incorrect Dr Ferenczi traces the controversy concerning the mechanical theory of traumatic neuroses He gives himself the pleasure of repeating a suggestion that some of the high sounding names originated by Oppenheim should be rescued from oblivion by being used as test words in disturbances of speech, and sums up the result of the controversy in the sentence "By degrees a marked silence fell over the mechanistic school" He is satisfied that an advance has taken place in the attitude of leading neurologists towards the teachings of psycho analysis

Dr Abraham contrasts the man who is repeatedly wounded and yet retains his mental stability with another who suffers a mental breakdown after a trifling stimulus and seeks an explanation of the contrast in the regularity with which the war neurotics were already labile people, especially as regards their sexuality He states that the symptoms observed in anxiety cases are similar to those seen in the impotent man or the frigid woman, and expects a similarity also in internal processes A diminution of sexual potency in traumatic neurotics had been noted by all taking part in the discussions

The symptomatology of the war neuroses is explained on a non sexual basis by Dr Simmel who describes cases in which tics, paralyses, or contractures represented terrifying episodes, the memory of which he restored under hypnosis or by dream exploration his methods are the same as those described by English writers But in cases which he has investigated more deeply as to predisposition he finds quite frequently "threads that lead down to the primordial network of infantile sexuality An attitude of father defiance" is found in those soldiers who broke down solely under the pressure of discipline

Dr Ernest Jones s contribution is, like the others of the series polemic, he points out that the individual incidence of the war neuroses demands the assumption of other factors besides the strain of war conditions and that the denial of unconscious mental conflicts by those who have not used some method which gives access to the unconscious is like a denial of the details of histology by those who have never looked through a microscope Although some symptoms—e g, dread of shells—may be coloured by war experiences no symptom occurs that is not met with in the neuroses of peace a fact which suggests that similar agents must be at work in both cases He describes the main principles of the psycho analytical theory of the neuroses as (1) their volitional origin, (2) the unresolved intra psychical conflict; (3) the unconscious wish (4) the influence of older unresolved conflicts, and (5) the primary unresolved wish, which is always of a sexual nature In the primary unresolved wish he finds the source of morbid anxiety, which he distinguishes from real or objectively justified, fear, the man whose libido has been repressed, whether that libido is directed to an outward object or inwardly as self love, possesses, in the fear arising from that libido, the potentiality of an out break of anxiety in time of stress Dr Jones sees no need for psycho analysis in the majority of cases, but regards a training in it as of the very highest value in treatment, psycho analysis is necessary when the condition has passed over into a peace neurosis and become consolidated

The book may be accepted both by friends and opponents, as an authoritative presentation of Freudian doctrine

---

OPERATIVE SURGERY

Second enlarged English edition By Prof VICTOR SCHMIEDEN and ARTHUR TURNBULL, M B, Ch B Glasg With Foreword by Prof BIER London Baillière, Tindall and Cox With 436 illustrations Pp xx-350 25s

BOOKS on operative surgery can be divided into two main classes those written for students and those prepared for the practising surgeon The former are supposed to give the student an insight into the principles of operative technique, whilst the latter furnish full details for the surgeon who may have to undertake any operation upon the living subject Prof Schmieden s book is a student s text book intended to serve as an accompaniment to a course on operative surgery It deserves the success which it has attained in that it is one of the few readable treatises on the subject describes a suitably representative series of operations, and is furnished with a useful collection of illustrations of clear but not too complicated a nature It is satisfactory to see that the customary over elaborate descriptions of the many types of amputation and of the ligature of arteries have given place to a more concise account of this section of the subject

British teachers may reasonably object to Prof Schmieden s disparaging remarks about Syme s amputation at the ankle, and to his advocacy of a method of intestinal anastomosis utilising but one row of sutures We find it difficult to understand why in a course intended for students the hand trephine should be referred to almost as a thing of the past A large number, if not the majority, of British surgeons still use the hand trephine It is astonishing to notice that a posterior incision in the middle of the popliteal space is preferred to a lateral incision for ligature of the popliteal artery The authors might with advantage have described more fully the operation of ligaturing piles and have made some reference to the inguinal operation for femoral hernia The book is well produced and easy to handle

---

Manual of Operative Surgery Eighth edition By JOHN FAIRBAIRN BINNIE, A M C M Aberd, F A C S London H K Lewis and Co, Ltd 1921 With 1628 illustrations Pp 1311 £3 3s

THE editions of Binnie s Manual seem to follow one another very rapidly—a sure indication of its usefulness and popularity This is no book for the student—for we do not think that even a senior student should do more than refer occasionally to such an exhaustive treatise—but essentially one for the practising surgeon to keep by him for constant reference The author is eclectic yet catholic His breadth of view has its drawback in that the inquirer may sometimes feel at a loss as to which of the many suitable methods he should adopt, but whilst including nearly all possible became practically synonymous with being a dyer, with this difference, that the professional dyer knew what he was about, while the histologist with few exceptions did not know, nor does he to the present day." His hope that this could be corrected may have been as exaggerated as his faith in the basis of technological practice, but his beliefs all centred round his impregnable ideal that structure and function must explain each other.

The earlier histologists knew this quite well; to BOWMAN the structure and function of the kidney were one problem. As the microscope became a commonplace and its technique developed, physiologists found, however, that the instrument which they looked to for the solution of their difficulties was raising as many problems as it was answering. Those who believe that the lung is a secretory organ say as little about the structure of the epithelium as they can help, and inflammation and immunity are long since divorced. In despair, we must suppose, of ever making form and function fit, physiology is now in general ready to throw histology overboard, that it may brighten the routine of anatomy. For the moment histology is at a discount among us, but it is not the histology that MANN taught. Some day a bright spirit will reappear, and will carry on MANN's inspired work, when probably "Physiologcial Histology" will go through many editions or form the inspiration for future treatises. The book is, of course, now out of date in many parts; the physical chemistry of proteids has advanced a long way since 1902. But it still indicates the line along which histology could be pursued with profit; fixers and stainers have not yet absorbed its chief thesis, which is that they ought to know more of the why and wherefore of what they do.

Accessible Hospital Records.

ONE of the difficulties with which a large general hospital has to deal is the accumulation of patients' notes. After a few years the mass of material becomes enormous and, as the *Hospital Gazette* has pointed out, the setting aside of storage room for the purpose is no easy matter. The suggestion is there made that many of the actual notes might be destroyed and concise records of each patient kept in a book under separate headings. Although the drawbacks of present methods are very great from the medical aspect, it is doubtful whether the system advocated would meet all requirements. In most large hospitals there is a registration department in which all the in-patient notes are collected. After a period of a year or so they are bound together to form unwieldy volumes, and in a big institution the number of such books rapidly increases until it becomes almost impossible to find space for them where they can remain easily accessible. The notes are often required for reference when a patient is readmitted or when a member of the staff wishes to investigate a series of cases. It is especially in looking up a large number of cases of a given disease that the present system is found so inadequate, for the notes are bound according to dates, irrespective of the nature of the disease. The notes of every individual case are kept, and space may be taken up by a number of nearly blank sheets and charts of a patient detained for a single night with some trivial ailment. Hence a search may involve the withdrawal from storage of a large number of bulky volumes, each containing one of the required cases. The books are heavy to carry about when the past history of a case has to be reinvestigated in the wards. There is also the grave disability that in-patient are separated from out-patient notes, and in the out-patient department there is at best a brief abstract of the in-patient findings.

These difficulties are overcome to a large extent by the method used in some departments of the London Hospital. On admission the patient has his notes taken by the surgeon or an assistant acting immediately under his supervision. The headings on the first page include only the name, age, and address of the patient, the name of the doctor, the date of admission, and the complete diagnosis on leaving hospital. The notes are kept in boxes in the wards and are not attached to a bed-board where they are apt to become soiled and torn. On leaving hospital the patient is given a dated card for attendance at the "follow-up" department, where his notes are card-indexed under the diagnosis and kept in alphabetical order in a box file. When a patient returns, the secretary of the follow-up department produces the notes for the surgeon to make additions; there is no break between in-patient and out-patient record. Trivial cases admitted to hospital do not come under the system; a record of them is kept in a book in the steward's office, with headings similar to those advocated in the *Hospital Gazette*. By this means a mass of useless material is abolished, and it is found that a small cupboard in the follow-up department will accommodate the whole of the notes for one surgeon for 15 or 20 years.

Such a method of note-keeping combined with a follow-up department deserves more general adoption. It is of value to the surgeon, enabling him to determine with accuracy the after-results of his treatment. It is of value to the patient who is seen at regular intervals, when any complication is noted early and adequately treated. It is of value in the organisation of the hospital; wards and out-patient department are not crowded out with old cases. The scheme may appear at first sight to throw extra work upon the staff, as an extra half-day a week has to be given to the examination of these cases. In practice, so great is the relief from interruption by old cases during an afternoon devoted to teaching that time may actually be saved. One half-day a week alone being required by each physician or surgeon, a follow-up secretary is able to control 11 departments. It has been suggested that, since each member of the staff has control of the notes of his own cases, difficulties may arise if an independent investigator wishes to look up a series. The reverse is the fact; instead of having to consult 50 or more large volumes he sees as many bound notes, which can be consulted with corresponding leisure.

UNIVERSITY OF LEEDS: A CHAIR OF BACTERIOLOGY.—Sir Edward Allen Brotherton, M.P., has given £20,000 to this university for the development of bacteriological study and research, more particularly in the interests of public health. This is the largest individual gift ever received by the University of Leeds. Sir Edward Brotherton, an ex-Lord Mayor of Leeds, who takes an active interest in many branches of public life, has been profoundly impressed by the importance of the study of bacteriology. He is chairman of the University Advisory Committee on the Department of Pathology and Bacteriology. This body includes representatives of the weekly board of the General Infirmary, of the Leeds City Council, and of the County Councils of the North, East, and West Ridings. The Department of the University of Leeds with which this committee is concerned is engaged in research as well as with the instruction of students, and also performs the bacteriological tests required by the public health department of the city, by the General Infirmary at Leeds, and by other bodies outside the city.

the Golgi apparatus, and mammalian embryological methods. He has also secured the assistance of many collaborators, all acknowledged masters in their subjects. Thus, Prof. W. M. Bayliss writes on staining; Dr. C. Da Fano has had charge of the section on neurological technique; Dr. A. Drew has rewritten the section on protozoa; Dr. W. Cramer is responsible for most of the article on fatty substances; and Mr. Thornton Carter has revised that portion which deals with teeth and bone. Numerous other authorities have been pressed into service, and the general result is a complete and stimulating manual. The best in the older teaching is retained, and the addition of the most modern methods of cytological research makes the book essential to the serious student of microscopic anatomy.

DAIRY BACTERIOLOGY.

By Dr. ORLA-JENSEN, Professor of Technical Bio-Chemistry in the Polytechnic College, Copenhagen; formerly Director of the Swiss Experimental Dairy Station. Translated from the second Danish edition, with additions and revisions, by P. S. ARUP, B.Sc., F.I.C., Chief Chemist, English Margarine Works, Ltd. London: J. and A. Churchill. 1921. With 70 illustrations. Pp. 180. 18*s.*

THERE is much attractive matter in this work. "Lactic acid" fermentation, the ripening of dairy products, and the abnormalities which may occur therein are subjects upon which the author has spent many years of patient study, and of which he writes with great authority. But the book suffers from excessive specialism. The classification of bacteria which is given fails to recognise adequately the great body of work carried out by those who are not necessarily directly concerned with the study of milk and milk products. The inclusion of *B. typhosus* and dysentery bacilli in the coliform group suggests a failure to recognise the work of MacConkey and many others. A similar failing is found in the section which is devoted to the production of milk, and the hope, expressed by the translator, that this book should be of use to those who are engaged in the production and distribution of pure milk, is hardly justified by the text, which does not lay down clearly the essentials of clean milk production. It does not appear that the author has made a study of the keeping qualities of "clean milk"; otherwise it is difficult to understand the statement that milk cannot be kept for "longer than 24 hours, even if cooled to 0°C.; if it is to be kept longer it must be frozen." The expert will, however, find most of the matter in this book of interest, and the student may read it with advantage if he be working under adequate supervision.

The translation has been admirably carried out, though some minor errors might be corrected in future editions. Metchnikoff did not spell his name with an "s," and flagellæ is not the plural of flagellum.

PRICES AND PRICE CONTROL.

Prices and Price Control in Great Britain and the United States during the World War. By SAMUEL LITMAN, Professor of Economics, University of Illinois. New York: Oxford University Press, American Branch. Pp. 331.

Prof. Litman contributes a summary of the incidence and effect of prices and price control in the United Kingdom and in the United States to the series of Preliminary Economic Studies of the War, edited by Mr. David Kinley, Professor of Political Economy at the University of Illinois. The Carnegie Endowment for International Peace is responsible for the publication of this series, and in his preface Prof. Kinley endorses the conclusions of the author, which, on the whole, do not attribute success to the legal control of prices, undertaken with the object of checking "profiteering." "Here and there," he writes, "a government is able to catch and punish a profiteer. But legal action on the whole has had little effect at any time in preventing or removing the evil practices that have called forth so much popular denunciation."

Scientific examination of the effect of price control during the late war, carried out in the clearer atmosphere of peace conditions and at leisure, is no doubt one of the steps to be taken in order to avoid mistakes in future, should anything so disastrous as war on a large scale again take place. Prof. Litman's book contains ample material for the consideration of those interested in general economics as illustrated by the question of how far the so-called "profiteer" was in fact responsible for the rise in prices during the war, or for the condition of workmen during that period of unprecedented demand and lessened supply. With regard to the commodities specifically discussed, we note that the chemical substances referred to are confined to those used in the manufacture of munitions, and that drugs used for medicinal purposes do not come under discussion.

THE BOY IN INDUSTRY AND LEISURE.

By the Rev. ROBERT R. HYDE. London: G. Bell and Sons, Ltd. 1921. Pp. 281. 6*s.*

IN his novel "Sybil," the late Lord Beaconsfield dealt with a number of social questions with real sincerity, and one of the characters makes the remark: "The youth of a nation are the trustees of Posterity." The youth of the nation to-day are in many ways different from those of the early forties; those who are left have passed through an ordeal such as our fathers never knew, but none the less are they the "trustees of Posterity," and this in whatever class of life they may move. The problem of the adolescent boy is by no means the least important of the many problems which exercise the minds of men to-day, and anybody who wishes for light on the subject will do well to read Mr. Hyde's book, for it is written by one who has spent a lifetime in dealing with boys and in organising agencies for their welfare. From his experience he comes to the conclusion that "the boys' club is the soundest form of organisation in spite of the attractions of the more disciplined methods of brigades, cadets, or scouts, but in stating this I do not, of course, belittle such organisations. I can but write from my own experience, and it leads me to that conclusion." Whether we agree with Mr. Hyde in this opinion or not, everyone interested in boys should read this book, and if they should feel tempted to become workers in the sense of running a boys' club or aiding in other ways, they will learn what to do and, that which is more important, what *not* to do from Mr. Hyde's pages. One of the most interesting sections is the account given by Mr. Hyde of the working of the Industrial Welfare Society. Mr. Hyde regrets the passing of the old-time feeling of personal relation between employer and employed; it is all but impossible to retain this under the modern factory system, although various firms have done and are doing their best. Even where it cannot be revived, the system of Industrial Welfare supervision goes some way towards healing the breach which has in too many cases been made between master and man. Mr. Hyde writes wisely and sympathetically, showing the sense of humour without which his life's work could not have been done.

JOURNALS.

PARASITOLOGY. Edited by G. H. F. NUTTALL, F.R.S. Vol. XIII., No. 3. August, 1921. C. F. Clay, Cambridge University Press. 15*s.*; yearly subscription £2 5*s.*—The number opens with an article by F. J. Meggitt on a New Cestode from the Pouched Rat of East Africa.—The paper on the Excretory System in Digenea Trematodes, by E. C. Faust, contains a description of the structure and development of the excretory system in cystocercous larva of *Cercaria pekinensis*.—The note on a Protozoon Pathogenic to Mosquito Larvæ, by W. A. Lamborn, deals with an unidentified protozoal infection in the larvæ of *Stegomyia scutellaris* in Federated Malay States. Material from Lamborn's collection was studied by D. Keilin, who in the two following papers described the structure and life-history of two new parasites of of single muscles. Much light has been thrown upon this problem by the work of Agduhr, who suggests that where a striped muscle fibre has more than one motor end-plate these belong to different segmental nerves. The second condition is of an entirely different order. This double innervation is constituted by the presence in the various skeletal muscles so far examined of non-myelinated motor nerve fibres, which are alleged to be independent of the ordinary myelinated motor nerve fibres not only in structural connexion but in origin. These so-called accessory motor fibres sometimes terminate in the same motor end-plates in which the terminals of the ordinary motor nerve fibres end; but they frequently end in accessory, independent, motor end-organs of characteristically smaller size. The work of Boeke from 1909 onwards has led to a fairly general acceptance of the evidence for a double motor innervation of striped muscle in this sense. He recognised the occurrence in muscle of a system of fine non-myelinated fibres which appear to him to be quite independent of the ordinary myelinated fibres; they showed characteristic termination in the shape of fine end-rings, loops, or nets. He laid stress upon their hypolemmal position and their often intimate association with the ordinary motor end-plates as witnessing to their centrifugal and quasi-motor function. In 1916 Boeke examined the end-plates in ocular muscles after section of their nerves; in 1919 Boeke and de Barenne published the results of section in a cat of the anterior and posterior roots of the sixth to ninth thoracic nerves inclusive, and of extirpation of the corresponding spinal ganglia; the condition as regards innervation of the muscles of the seventh intercostal space was investigated after the lapse of a period of one month; in the same year Agduhr investigated the interossei muscles in the cat. Prof. Wilson concludes that it is difficult, if not impossible, to avoid the deduction, drawn by Boeke, Agduhr, and others from their crucial experiments, that the accessory fibres are sympathetic in origin and hypolemmal in their mode of termination. These relationships, if admitted, would indicate a centrifugal conduction of nerve impulses, presumably of motor and possibly of tonic contractile character.

PARA-MEDICAL RESEARCH.

THE report for 1920–21 of the Committee of the Privy Council for Scientific and Industrial Research[1] touches the fringe of several medical problems and describes work linked at several points with that being undertaken under the auspices of the Medical Research Council. For example, it is at the suggestion of this Council that a subcommittee of the British Scientific Instrument Research Association, in coöperation with the Electro-Therapeutic Section of the Royal Society of Medicine, is drawing up a specification of an X ray outfit complete with modern requirements. On the medical aspect of the work of the National Physical Laboratory, again, we have recently commented.[2] The Deep and Hot Mines Research Committee records progress in the control of atmospheric conditions in mines; experiments on the effects of high temperatures on the output of the mine-worker are said to have yielded results of considerable interest. The Food Investigation Board anticipates that the new low temperature station for research in biochemistry and bio-physics now being erected at Cambridge will be complete at the end of this year. Prof. W. Stiles has prepared a memoir, now in the press, on the general theory of the preservation of food by cold, from a physiological standpoint. In the course of a general study of the phenomena of putrefaction the conditions determining the production of lactic acid in muscle have been the subject of investigations by D. L. Foster and D. M. Moyle; G. S. Graham Smith has attempted to ascertain the factors which determine the rate of multiplication of bacteria, while W. G. Savage has published a study of the effect of a diet containing putrefying foods upon the health of animals. Other reports on the bacteriology and chemistry of canned foods are nearing completion. Experiments on cooking and heating stoves, on the transmission of heat and gases through wall materials, and the condensation of moisture on their surfaces are being made. In view of the importance of formaldehyde in the manufacture of disinfectants, and of the fact that supplies are at present almost entirely imported or made from imported materials, the Chemistry Coördinating Research Board proposes to investigate the possibilities of its production in this country. The Oxygen Research Committee announces that a handbook is in preparation embodying the more important results of its inquiries and experiments, and giving some account of the general methods of production and the application and uses of oxygen. The types of gas cylinders most suitable for use in hospitals and for mine rescue work are also being considered by experts.

These few examples of investigations undertaken under the auspices of a committee of the Privy Council with the primary object of advancing science and industry rather than medicine are sufficient to show the interdependence of all scientific research. The desirability of the direction of medical research towards industrial problems has been sufficiently emphasised of recent years; we hear less of the advantages to medicine of research in other fields. The results obtained from these investigations may suggest fruitful lines of inquiry on an entirely different aspect of a subject, and, as is argued in this report, even irregular or unexplained results may often form the starting point for important advances on a side issue. We therefore commend this important and suggestive report to the attention of our readers.

NUTRITIONAL KERATOMALACIA IN INFANTS.

KERATOMALACIA, of which Dr. S. G. Ross,[1] of Baltimore, records four illustrative cases, is an infantile ulceration of the cornea with xerosis of the conjunctiva, the rarity of which is shown by the fact that these were the only examples of the condition among more than 28,000 admissions to the children's department of the Johns Hopkins Hospital. The relationship between this type of corneal disease and malnutrition in infants was first noticed by W. Mackenzie in 1857, and was confirmed by subsequent writers, among whom we may mention Holmes Spicer,[2] who in 1892 observed the condition in England only among artificially reared infants, who had a diet lacking in nitrogenous elements. He also noted that it was not uncommon in countries where nursing mothers practised long fasts. In 1904 Mori described a disease prevalent in Japan among children aged from 2 to 5 years, and characterised by diarrhœa, excessive appetite, swelling of the abdomen, loss of weight, night-blindness, dryness of the skin and hair, and xerosis conjunctivæ. Breast-feeding in such cases was almost universal for a year, and subsequently the diet consisted almost entirely of cereals and some vegetables. In the course of four years Mori observed 1511 cases of this disease, of which 116 developed keratomalacia. In 1906 Czerny and Keller, in their description of "Mehlnährschaden," a nutritional disease in infants due to an almost exclusive diet of carbohydrates, drew attention to keratomalacia as one of the complications. In 1917 McCollum and Simmonds suggested that lack of the accessory substance, which McCollum in 1916 had named "fat-soluble A," was the cause of the deficiency disease both in young rats and infants. In Dr. Ross's cases the children had been fed almost exclusively on condensed milk, a food high in carbohydrate value, relatively low in fat and protein, and probably deficient in the fat-soluble A factor. The prognosis of keratomalacia is grave in infants, but improves

Health Insurance and the State.

WHEN considering the question of the remuneration to be paid to practitioners on the panel there is one point which, although of vital importance to the medical profession as well as to the State, is apt to be overlooked. Cost of living, inflation of the currency and the like are, of course, urgent matters for consideration, but all these deal with the present and are matters which may be met and remedied as time passes and opportunities occur. It is the doctor's future to which attention should be drawn, and for which provision should be made. The doctor, no less than other folk, looks forward to an old age which shall be, if not one of ease, at any rate one unhampered by anxieties as to the actual means of existence. He may be able by means of insurances of one kind and another to make the necessary provision; he may be able by lucky investments to place himself in a position which frees his future from care. There has, however, always been one source to which the general practitioner has looked for considerable assistance towards his retirement—that source has been the capital value of his practice. When the Insurance Act was introduced, the fears which beset so many practitioners were both falsified and fulfilled. Fulfilled in that where his practice lay in an industrial area the value of his private work declined by 50 or even much more per cent.; falsified in that he was able to replace the loss by a practice which had become more valuable owing to the ease of transfer of his list of insured persons. This value will largely be destroyed by the action of the new clause entitled "Change of Practitioner" inserted in the Medical Benefit Regulations for 1920, and once destroyed it will not be restored.

Whether the destruction of the capital value of insurance practices is a good or a bad thing is beside the question, which is: How is the doctor to make good the loss of an interest which the Insurance Act did not create although it may have appreciated its value? What is to replace this lost capital asset? Publicans receive compensation for the abolition of licences, civil and other public servants whose offices may be discontinued are recompensed. Nothing has been heard of any suggestion for the recompense of the practitioner, although there would appear to be no more valid reason why he should not benefit from the value of the goodwill of his practice than for a similar disability in the case of the grocer or draper. On the other hand, it is now proposed to reduce the remuneration of the panel doctor, thus further limiting his power to make a provision for old age. Those who may negotiate on behalf of the panel doctor should bear this point of view in mind, and it seems possible that those negotiating on behalf of the Ministry of Health might be able to see that to give the doctor the opportunity of providing for old age is one means of providing a contented and consequently efficient medical service. If economy is the reason for the suggested reduction of the capitation fee, that object would be attained if the Government were to credit panel practitioners each year with the amount, or part of the amount, of the proposed reduction, at the same time making the desired provision for old age. The sum so credited could form a sinking fund out of which practitioners of certain age and service, might receive annuities, the actual amount to be settled by actuarial calculation.

The advantages to the doctors of some such system are manifest, whilst the advantages to the State are equally clear. The capital sum could be used to meet some of the more pressing needs brought about by the financial conditions now prevailing. Such a fund would eventually be self-supporting. The suggestion is not a new one. As Dr. H. H. MILLS reminded our readers last week, it has been before both parties since 1913, and concrete proposals were laid before the Panel Conference of 1919. We are glad to note that the subject of provision for the superannuation of practitioners is to be brought by resolution before the conference which meets next week, when the Government proposals for reduction will be considered (see p. 829).

◆

Physiological Histology.

GUSTAV MANN, who died at Tampico in Mexico on July 18th, after an acute attack of dysentery, was a leader in his branch of medical work. He will be chiefly remembered by Oxford students of physiology under Prof. GOTCH, in whose department he was demonstrator, and in charge of the teaching of histology from 1894 to 1908. His vivid, freakish, sometimes impish, personality is not easily forgotten, and many pupils, grateful for a revelation of what histology might be, felt a real sense of loss on his translation to America, where he occupied the chair of physiology in the Tulane University in New Orleans, till his consummate skill in the gentle art of making enemies led to his drifting off into the less academic occupations of the last five or six years of his life. That MANN was easily the first histologist of his day in this country there can be no question; his technical skill was unsurpassed. But what he stood for in histology has found no representation with us since the sad death of his pupil and successor at Oxford, S. G. SCOTT. He saw quite clearly, and constantly emphasised in his teaching, that histology was not a department of knowledge but an item of the apparatus which should help to elucidate the general laws governing biological phenomena. It comprises, he said, "investigations into the structure, the chemical composition, and the functions of healthy and diseased animal and vegetable cells." Histology was to him a part of physiology, and he looked on micro-anatomy as its elementary introduction. The difference between this point of view and that more commonly held may be appreciated by comparing his "Physiological Histology" with, for instance, the "Microtomist's Vade-Mecum," a hardy perennial which has blossomed again this season.[1] This excellent manual sets out to tell us what has been done and how to do it, while the "Physiological Histology" in addition conjures up a vision of what might be done and how most likely we might do it. The main idea that ran through MANN'S own restless and vagarious work of brain and hand was that a fuller knowledge of the chemistry and physics of protoplasm and of dyes would lead to our recognition of the nature of cell constituents as certainly as we identify inorganic iron by the Prussian blue reaction. "The method of staining grew and grew," he said, "till to be a histologist between 5 and 15—and its prolonged prodromal stage. From the fourth disease pseudo-rubella is distinguished by its long prodromal period, slower progress of the eruption, character of the rash, lack of contagiousness, and absence of throat symptoms and desquamation. Dr. Westcott concludes that the condition described is a mild infection, non-contagious, or only feebly contagious, to which young infants are particularly susceptible and older children not all or only rarely liable.

NEW SPECIMENS AT THE ROYAL COLLEGE OF SURGEONS.

AMONG the recent acquisitions by the museum of the Royal College of Surgeons which are now on show at the annual exhibition are a series of specimens from the Onodi collection which was presented to the college early this year. This collection, as we have previously noted, illustrates the surgical and pathological anatomy of the nasal fossæ. Perhaps the most remarkable specimen of these yet mounted is one (No. 29) of a choanal polyp, which springs from the wall of the right maxillary sinus. It has widened the opening of this cavity into the nose and is seen passing forwards and backwards towards the anterior and posterior nares. From a crypt on the nasal surface of the polyp a barley-corn with husk was found. As it is a wet specimen and has been preserved in spirit it is pretty certain that this gained access to the nose during life. Until more specimens have been cleaned and mounted it has only been possible to allot temporary numbers and to make a provisional classification. This divides the specimens into those showing relations of the cavities as a group to surrounding structures, those showing the average normal anatomy of various sinuses, and those showing normal but unusual anatomy of the sinuses and pathological specimens. In the first three groups there is much overlapping, and it is not yet certain whether such a classification can be retained.

CRIME AND MENTAL DEFICIENCY.

THE relationship between crime and mental deficiency is a matter not only of considerable philosophical and scientific interest, but also of great practical importance. It is, moreover, one regarding which it is very desirable that the medical practitioner should be well informed, since he is not infrequently called upon to deal professionally with both crime and mental defect. Unfortunately the instruction he receives during the ordinary medical curriculum is far from adequate, and it was for the purpose of remedying this that the University of London has instituted a special course of post-graduate lectures and clinical instruction on the subject of Mental Deficiency. In this issue of THE LANCET we publish a lecture given at this course by Dr. W. C. Sullivan on Crime and Mental Deficiency, which should prove of considerable value in the elucidation of this problem. As Dr. Sullivan points out, although the statement is often made that crime is the result of a special criminal diathesis or temperament, this is a view which requires a good deal of qualification. Crime, in fact, is not a biological concept at all, but a legal one, and, moreover, a concept which not only differs very greatly with different races, but even with the same race at different periods. Man inherits certain deeply ingrained impulses to action from his remote past which are for the most part essentially egoistic; in the course of time it is found that the manifestation of these impulses conflicts with the well-being of the community as a whole: in consequence laws are made and standards set up for the regulation of his conduct, and the person who violates or fails to conform to these standards is a criminal.

It is probable that most normal persons are potential criminals, for they possess these primitive impulses to action: they are, however, not actual criminals, inasmuch as they have developed in addition certain inhibitory qualities which enable them to modify and restrain these impulses in accordance with the standards of their society. Upon what does this conformity or non-conformity depend—in other words, what is the psychological basis of misconduct? No doubt the mental factors concerned are highly complex, and our knowledge regarding them is admittedly still imperfect; we may, however, specify three which, undoubtedly, have considerable influence in the regulation of conduct—namely, knowledge of the requirements of the law, sense of social or moral obligation, ability to learn from experience and to appreciate the personal disadvantage resulting from certain acts. These inhibitory processes may, of course, be disordered, as in cases of insanity; they may, however, be primarily defective, and this is the case with many persons suffering from mental deficiency. It is therefore not surprising to find that crime is relatively far more frequent in aments than in those of normal mental development, and whilst statistics on this point are not free from certain fallacies it is significant that while the proportion of aments in the general population is about 0·5 per cent., the proportion of aments in the prison population is from 10 to 20 per cent. This point, which is really only one aspect of the problem of the mentally defective, raises the question as to whether the decision to postpone providing adequate provision for this class on the plea of economy is really an economical process for the nation. There is, however, another class of defectives who are even more closely related to crime—in fact, who are incorrigible criminals and whose lives are one long record of crime and social danger. This class has long been known to psychiatrists, but has only recently received legal recognition, and there is no doubt that much misapprehension still exists concerning it. We refer to the class of moral imbeciles.

As was pointed out in a recent address before the Royal Society of Medicine by Dr. A. F. Tredgold,[1] moral imbeciles differ from ordinary defectives in that they present no inability to learn in school and no defect of that lower level of intelligence which is concerned in the adaptation of conduct to the immediate requirements of the moment; on the contrary they are often well educated, plausible talkers, of prepossessing appearance, and decidedly cunning, so much so that persons with a limited knowledge of psychological medicine have the greatest difficulty in realising that they can be defectives. Nevertheless, they are defective in certain constituents of mind which are of vital importance in the regulation of conduct, and it is such defect which brings them within the definition given in the Act. Dr. Tredgold states that there are two psychological processes which are thus defective in the moral imbecile—namely, moral or social sense, and that higher form of intelligence which enables an individual to adapt his conduct, not merely to the requirements of the moment, but to those of the more remote future; this was designated "wisdom" by the late Dr. Mercier, and is popularly known as common sense. It is shown that defect of moral sense is not in itself sufficient to account for persistent crime, and as a matter of fact there are many persons amongst the ordinary population whose moral sense is decidedly weak, but who are not criminals for the reason that their wisdom tells them that should they be detected the disadvantages would be greater than the advantages; they may, however, commit occasional crimes if the circumstances are such as to lead them to think that they will not be found out. The moral imbecile, on the other hand, is lacking in both wisdom and moral sentiment; in consequence his primitive self-seeking impulses have full and unfettered play and he is a persistent and incorrigible criminal. There can be no doubt that this condition of moral imbecility is one of very great social importance,

Annotations.

"Ne quid nimis."

NORMAL CONTROLS IN PATHOLOGICAL INVESTIGATIONS.

A PAPER such as the Gastro-enterological Number of the *New York Medical Journal*,[1] which has just reached us, intensifies the importance of securing adequate controls in all pathological investigations. On the one hand we read of laboratory investigations whose complexity and difficulty must place them beyond the purse of the average patient, and, on the other we learn of huge institutions, excelling in size and equipment anything known in Europe, where cases are dealt with in enormous numbers—followed, as the authors allow, by doubtful success—and are treated by methods which differ radically from one another in the various clinics. Economic considerations will prohibit a similar state of affairs in England for many years to come. But we are tempted to ask whether our patients, with the careful attention of our more individualistic clinicians, may not gain, at any rate in some directions, by our lack of organisation. We read of gastric analyses involving one or more test-meals and several gastric lavages, followed by estimations of acid, bile content, mucus, blood both free and occult, trypsin, pepsin, pepsinogen, rennin, renninzymoza, and half a dozen other chemical constituents, with cytological examination for six different types of epithelium and some dozen groups of bacteria, yet nowhere in this same article do we find evidence as to the frequency of occurrence of parallel findings in the normal healthy person. In another article in the same journal we read the latest investigations of Prof. Max Einhorn, who momentarily abandons the "gastric bucket," the "duodenal thread," and the "intestinal delineator," in order to describe the biliary secretion excited by a formidable variety of salts and other chemical substances; but here we note that Prof. Einhorn's conclusions are drawn from four patients only, and that all of them were suffering from grave organic disease. Nor is Prof. Einhorn alone, for in this same journal are two other articles, by well-known American physicians, describing elaborate diagnostic and therapeutic procedures in cases of disease of the biliary passages, all based upon the original observations of Lyon, that instillation of a strong solution of magnesium sulphate into the duodenum is followed by an outflow of bile. But is there existent any series of experiments on normal men which can allow comparison to be made with the findings in these pathological cases? If these refinements of laboratory technique are to have any permanent utility—and surely amongst these laborious American researches there must be much which is of value—it is clear that laboratory work on the healthy individual must be brought into a far more prominent position that it holds at the present day. Each year adds to the syllabus of the overworked medical student, but it should be possible, by judicious modification of the usual methods of teaching physiology, to send him to the wards already conversant with the technique of investigation which he there sees applied to patients; and the same method would supply to the clinician those normal standards of comparison whose absence at present may lead him into errors of the gravest kind. To those of us who have come to think of America as the land where the ideal medical clinic exists as a reality there is something of sacrilege in the article by Dr. Wendkos, of Philadelphia, in the journal under discussion, wherein he speaks of the serious percentage of gastric cases which leave even the Mayo clinic undiagnosed, some of them to return with inoperable carcinoma; or of the statistics of cure at the Sippy clinic, figures which, he implies, are altogether erroneous owing to the original diagnosis of gastric ulcer having been made on inadequate grounds. No less surprising is his description of a hospital where the gastro-intestinal patients are indiscriminately, for "experimental purposes," treated by psychotherapy. At a time when medical progress in England is severely handicapped by economic distress there is perhaps a grain of comfort in the reflexion that we are left in possession of our proverbial British phlegm.

THE LIFE OF METCHNIKOFF.

A BIOGRAPHY[1] of Elie Metchnikoff by his wife, now available to English readers in a very readable translation by Mrs. R. L. Devonshire, gives fully and with the intimate sympathy that would be expected an illuminating account of the man—his impressionable childhood, his wonderful growth as a university student, the emotional lapses that led him to two attempts on his own life, the calm of his later years with their passionate desire to find a philosophy of human existence which should make it better. And we can form a pretty clear picture from the personal details which help so much to explain what a man does and are so often missing from biographies. The narrative of Metchnikoff's scientific work is less satisfactory: it seems to lack sequence and fails to place in its proper perspective the discoveries for which he is and will be most famous. It was in 1882, at the age of 37, that he appears to have definitely conceived the idea that wandering cells might defend the body against foreign and injurious particles by taking them into their substance and digesting them, and till about the end of the century his energies were entirely devoted to the development and elaboration of this into a complete theory of immunity. Up to a point all went well, but when the newer knowledge of the production of antibodies and their humoral action came along he failed to convince his fellow workers that the phenomena were just an extension of his "doctrine" of phagocytosis, as Sir Ray Lankester calls it in a reminiscent preface to the translation. The account given in this biography would lead the general reader to suppose that Metchnikoff really succeeded in "proving" that antibodies arise from leucocytes either by their disintegration or by an exaggeration of their normal digestive processes. This is hardly a fair valuation of his attempts to decide a very difficult question which still evades complete solution. We have noticed evidence of defective technical editing in the footnote on p. 175, where "immunising body" is given as a synonym of his "fixator," and on the following page where "cytasis" twice can hardly be a misprint. The truth of the matter, as we pointed out[2] at the time of Metchnikoff's death, is that in the controversies in which Metchnikoff represented one side and Ehrlich the other extreme, both parties turned out to be partly right—and modern bacteriological research is blending the views of the German "humoral" and the French "cellular" school into a harmonious whole.

INNERVATION OF STRIPED MUSCLE.

MANY papers have recently been published under the title of the Double Innervation of Striated Muscle. In the current issue of *Brain* Dr. J. T. Wilson, F.R.S., Challis professor of anatomy in the University of Sydney, regards this title as unsatisfactory because it ignores the distinction between the sensory and motor innervation of the muscle tissue. Even if we substitute the expression "double motor innervation" there remains the objection that two very different conditions as regards the motor nerve supply of muscle have been recognised, either of which may well enough be brought into this category. The first of these is the plurisegmental innervation deduced probable conclusions from certain data. The cause of typhoid was, moreover, variously attributed in different places: in Belfast to cockles, in Germany to the healthy carrier, in certain Scotch and American cities to milk, in the South African and the Spanish-American war to flies. Few who studied Bulstrode's elucidation of the case of the Winchester and Southampton banquets could fail to suspect oysters, even though the drains of the houses of some of the sufferers failed to pass the water test, and though the housekeeper of one sufferer, or the aunt of another, had become a typhoid carrier 20 years previously. In the *light of recent knowledge some of the reports* of earlier epidemiologists make fascinating reading. When the facts of the prevalences of typhoid in the Tees Valley, Belfast, Newport, Worthing, Bangor, and King's Lynn, which had been attributed to water pollution, were reviewed in the light of shell-fish pollution, the verdict against the water seemed less clear. In connexion with supposed food infections, especially milk, Dr. Hamer referred to the complication of the healthy carrier. The case for estuarial pollution versus the oyster-barman-carrier has been fully argued elsewhere.

[1] Life of Elie Metchnikoff. By Olga Metchnikoff. London: Constable and Co. 1921. Pp. 297. 21s.

[2] THE LANCET, 1916, ii., 159.

The broad fact emerging from Dr. Hamer's review is *that London typhoid for the* past 25 years has been in the main of estuarial origin. He discussed certain supposed milk outbreaks, excluding those involving less than 20 cases, and those in which it was stated that less than 95 per cent. of the sufferers were consumers of the suspected milk. Of 110 outbreaks, collected mostly from records in the British Isles, only 22 passed these tests. It was apparent in these records that no study of other possible food infections had been made, and the milk theory could only be accepted *faute de mieux*. A percentage of even 100 consumers affected might well not justify this theory. An early outbreak attributed to milk was that reported by Dr. M. W. Taylor, in the *Edinburgh Medical Journal*, 1857–58, and Dr. Hamer concluded from a study of this report that the disease was probably typhus and not typhoid. Almost the first case published was that of the Islington outbreak of 1870, reported on by Dr. Ballard. Dr. Hamer concluded from his analysis of this report that the *distribution of infected fish or shell-fish was a possible* explanation of the outbreak. He also pointed out various difficulties connected with the attribution of the Marylebone outbreak of 1873 to milk, remarking that an investigation of the incidence of illness upon customers of a certain fish shop a few yards from the suspected dairy might have been of considerable interest. He referred to other outbreaks attributed to milk, maintaining that the relationship might have been explained as a coincidence. Again, in 1891 four groups of cases in Rotherhithe, Deptford, and Greenwich were reported on by Dr. George Turner, and a prima facie case was made out against certain ice-cream supplies. Dr. Hamer submitted reasons for regarding these and other outbreaks in London at about the same time as being possibly due to infected shell-fish or other fish. He had investigated a Finsbury outbreak in 1911 with Dr. A. E. Thomas, and was able to show that ice-cream was not at fault, as was at first suspected, but a fried-fish shop just opposite that of the ice-cream vendor. Finally, he referred to a Plumstead outbreak in 1895, which he investigated with Dr. Sidney Davies, and accepted at the time as a milk outbreak. Some years later he learnt that the suspected dairy was next door to a fish vendor, and from the incidence of the case the explanation was a matter of doubt. Dr. Hamer claimed *that this examination of reputed London* milk outbreaks confirmed the view held by Creighton that if milk must be deemed a cause of typhoid epidemics, it could only be held responsible for certain aberrant prevalences of a typhoid-like disease, and was not a significant factor in the spread of true typhoid fever. He said that high typhoid death-rates were to be found in coastal areas or in areas within easy road or rail communication with these, with centres of fish distribution. The areas with low typhoid rates were almost without exception remote from such districts, and this was all the more striking because these areas were just those where primitive methods of drainage and water-supply still prevailed. Dr. Hamer concluded "that a bird's-eye view yields unmistakable indication that, at any rate, during the last 25 years, the mischief responsible for London typhoid has been found in some remote estuary or on some far distant foreshore."

THE HOSPITAL FOR TROPICAL DISEASES.

Owing to the depression of trade the number of cases of tropical disease admitted to the London Hospital for Tropical Diseases from the docks and ships in port has become small. It is important to secure sufficient clinical material for study in London and for teaching purposes, and a leaflet has been issued by the hospital, in association with the London School of Tropical Medicine, explaining that patients suffering from any form of tropical disease may make application to the secretary for treatment, special arrangements being made for women and children. Those who can afford it are expected to pay towards the cost of their treatment, and suitable cases are accommodated in private wards. The hospital offers special facilities to those who are taken ill on board ship or who are invalided from the tropics with malaria, dysentery, sprue, or with any form of fever or tropical disease, and arrangements can be made to receive them straight from the ship. The honorary medical staff will be glad to hear from medical officers in the *services, or in private practice*, with *regard to* patients needing expert treatment.

The Hospital for Tropical Diseases is now situated in Endsleigh Gardens, Euston Square, N.W., within easy reach of several main London termini, while an ambulance service is maintained between the new hospital and the old one in the Albert Docks, where the school once stood. Cases are admitted there straight from the ships in the East London Docks.

The Federation of Medical and Allied Societies has now moved into new offices at 12, Stratford-place, Oxford-street, London, W. 1.

The news is announced of the death of Dr. Theodore Schott, well known for his treatment at Bad-Nauheim of cardiac disease.

The Guild of St. Luke Annual Service will this year take the form of a special thanksgiving for peace. The service will be held on Tuesday, Oct. 18th, at 7 P.M., the preacher being the Rev. Father Waggett. The offerings, after defraying the cost of the service, will be devoted to one of the hospitals in London. Doctors and students are requested to wear academic dress.

We publish this week (p. 833) a plea for the better use of vital statistics in public health by Sir Arthur Newsholme, formerly Principal Medical Officer to the Local Government Board. The address was delivered at a dinner held in Sir Arthur Newsholme's honour by the American Statistical Society on the eve of his departure for England.

Sir Marriott Cooke and Dr. Sidney Coupland, consulting physician to the Middlesex Hospital, have retired from their position as Commissioners of the Board of Control. Both of them were appointed Commissioners in Lunacy in 1898, and the former, who was previously medical superintendent of the Worcester County and City and the Wiltshire Asylums, acted during 1916–18 as chairman of the Board.

THE LANCET of January 1st, 1921.

The Manager will be obliged to readers who have not any further use for their copy of The Lancet of the above date if they will kindly return it to him at 1, Bedford-street, Strand, W.C. 2. The postage on the number is three halfpence. He will be pleased to pay for those returned.

greatly above the age of 1 year. Death results from nutritional disturbance, and the eye lesion is an indication that this is far advanced. Three of Dr. Ross's cases died, two from broncho-pneumonia. Treatment consists in supplying a sufficient quantity of animal fat which contains the fat-soluble A factor. If breast milk is not available, cow's milk should be employed. The use of cod-liver oil, which acted as a specific in the Japanese cases observed by Mori, should be begun immediately in doses of 5 minims, three times a day.

UNIVERSITIES' LIBRARY FOR CENTRAL EUROPE.

THE first year's report of the Universities' Library for Central Europe has now appeared. The name of the library has been changed from "The Anglo-American University Library for Central Europe," as a result of the decision of the United States workers to carry on with their separate organisation of supply. It is announced that the results of the appeal, whilst enabling a great deal to be done towards renewal of stocks of English literature in Central European universities and libraries, has not been sufficient to allow of large-scale "literary relief." So far, more than 2000 separate treatises have been despatched, in addition to a large number of scientific reviews and periodicals, and journals and transactions of learned societies. A special letter, sent to every periodical and journal which had been asked for, brought excellent results; in a number of cases five or six complete sets of various journals for the war period were despatched to the continental centres. The number of consignments of literature sent to the centres was as follows: Austria, 17; Czecho-Slovakia, 4; Esthonia, 1; Germany (4 centres), 21; Hungary, 5; Poland, 4. Many of the continental universities have again been put into touch with English scientific societies with a view to an exchange of publications; reduced subscription rates have been secured for a number of important scientific journals, and other facilities for transmission of gifts of literature have been arranged. An appeal was issued to all publishers asking for special credit and other terms to continental universities, but only the Oxford University Press sent a favourable reply. The Society of Friends undertook the transport of consignments at their special rates. Parcels for Czecho-Slovakia and Esthonia were collected and transmitted by the respective Legations, and it is hoped that it will be possible to extend this practice to other countries. Comparatively limited as has been the number of books sent, their distribution has been highly appreciated on the Continent. The library has undoubtedly justified its existence, and it is to be noted that generous support in the form of money and books is still urgently needed. The names of the donors of literature and the audited balance sheet are included in the report.

THE CONTROL OF SURGICAL MENOPAUSE.

EVERY operating gynæcologist has seen troublesome results follow a sudden cessation of the internal secretion of the ovaries. Dr. Albert Groves Hulett, of East Orange, New Jersey, having had some distressing experiences with patients after oöphorectomy or pan-hysterectomy, devised a routine administration of ovarian extract which has been successful in making the induction of the artificial menopause a gradual one, unaccompanied by any mental distress. His technique[1] is as follows: "Starting on the fifth day after operation the patient is given 5 gr. of ovarian substance in tablet form four times daily. This dosage is continued for one month. For the next two months three doses of 5 gr. each are administered daily. Throughout the succeeding three months the dose is 3 gr., three times daily; during the seventh and eighth months the patient takes 3 gr. twice daily; and during the ninth month 2 gr. twice daily. In the tenth month 2 gr. are taken each night upon retiring; in the eleventh month 2 gr. on retiring on alternate nights; and in the twelfth month 2 gr. upon retiring every fourth night." Dr. Hulett has the advantage of experience in this method, which he does not claim as original, and it would, therefore, seem unfair to criticise his technique. It would be interesting to know, however, whether any extensive trial had been made of an acclimatisation extending over say 3 months instead of 12. With his further advice that the patient should resume, as soon as possible after the operation, all her normal habits of living everyone will be in cordial agreement.

DEVELOPMENTAL ABNORMALITIES.

MEDIAN hare-lip is of very rare occurrence. In the current number of *Dental Cosmos*, Dr. S. L. Silverman reports an example of it, associated with completely closed palate, a simple median nostril, and complete absence of external nose. There was also an encephalocele. Median hare-lip is known, at any rate by report, to all students interested in facial deformities, and in this case is evidently due to the want of development of the fronto-nasal process. The perfect palate is enough to indicate that the maxillary processes possessed their growing power, but it is not impossible or unlikely that the portions of these processes which reach the middle line of the roof of the general mouth-cavity, and reach and aid the growth of the fronto-nasal process, were defective in association with the failure of this latter region. The short report throws no light on this point, but if the assumption is correct it follows that there can be little or no provision of a mesodermal bed in the depths of which the nasal fossæ could grow to their full height, whence the smallness of the fossæ. It would seem not improbable that the so-called median single nostril may be but an appearance on the surface, the overlapping maxillary growth hiding the small undeveloped nasal fossæ. But nothing short of careful serial sectioning would enable a thorough explanation of the specimen to be given.

PSEUDO-RUBELLA.

Dr. Thompson S. Westcott,[1] associate in diseases of children of the University of Pennsylvania, applies this term to an eruptive disease of which he has observed isolated examples during the last ten years in infants between the ages of 8 months and 2 years. The onset is abrupt, with a rise of temperature to 102° or 103° F. There is no cough, coryza, lacrymation, nor conjunctival irritation. The fauces are normal. The following day the temperature remains high, and nothing new is found except slight enlargement and tenderness of the posterior cervical glands. The posterior auricular and axillary glands are not affected, but in some instances the inguinal glands are involved. During the next two days the temperature remains raised, and on the evening of the fourth day a few discrete red macules appear on the neck, face, under the eyes, or above the clavicles. On the fifth day the temperature is lower, the rash is more marked, covering the face, neck, chest, and shoulders. It is more discrete than a rubella rash, and not raised above the surface, but in some areas, especially the loins and thighs, it shows a tendency to coalesce. On the sixth day the temperature and pulse are normal, and the rash begins to fade, disappearing in the next two days without any subsequent desquamation. In spite of its resemblance to rubella in the appearance of the rash, enlargement of the posterior cervical glands, and febrile course, pseudo-rubella differs from it in its non-contagious character, its age distribution—the disease being confined to children under 2, while rubella is most frequent being the cure of disease, pharmacy was no longer called upon to relieve its symptoms, but still had to provide the necessary materia. Sir David Prain pointed out that pharmacy concentrates upon the "qualities" of the materia, while medicine studies their "uses." Should the new policy of medicine succeed, these materia would be converted into historic lumber, and pharmacy must undergo a corresponding modification. In husbandry the desirability of a practical pupilage had not yet been questioned. Still, the question had resulted in two schools of thought: some regard practice alone as sufficient training, while others prefer practice with science, but maintain that practice should precede training in pure science. Among those who advocate training in pure science there was again a divergence of opinion. Some think that practice and scientific training should proceed concurrently, while others prefer that practical pupilage should precede the course in pure science. In schools of agriculture the result of experience had led, in some cases, to the abandonment of the concurrent system at one time adopted, and in future only such pupils would be admitted as had undergone a prescribed minimum of practical training. In horticulture, generally speaking, nothing was allowed to interfere with the practical pupilage which, on completion, was followed by the study of pure sciences.

---

[1] The Induction of Gradual Normal Menopause after Ovariectomy, Medical Record, August 27th, p. 369.

[1] American Journal of the Medical Sciences, September, 1921.

Sir David Prain explained that in callings like pharmacy and garden-craft four distinct types of training were to be found: practical pupilage alone or a training in pure science (1) as a prelude, (2) as a complement, or (3) as a supplement to practical pupilage. Pupilage alone was both instructive and educatory, but education suffered because the primary aim of the teacher was instruction in the art of doing things, the pupil being largely left to his own devices to learn the underlying principles. Science before practice was good in theory, but might fail in practice because there was a tendency to put the apparently burdensome pure science entirely on one side when the examination had been passed and to forget the distasteful study as rapidly as possible. The objection to pursuing science concurrently with practice was that it is best to do one thing at a time. The interest of a good pupil in his calling was so intense that it absorbed his attention so fully as to render him incapable of giving proper attention to the underlying sciences. Science after practice seemed to be the ideal arrangement. The pupil had made his craft a part of his individuality, and immediately grasped the relevance of the scientific facts now placed before him. He would follow his studies with a keenness and interest that made them a pleasure alike to teacher and taught. Should pharmacy find herself eventually compelled to abandon pupilage as medicine had done, she might, as regards physics and chemistry, rely upon the aid of academic science, as did agriculture and medicine. But so far as biology was concerned she would do well to impart the scientific training on her own account, because the academic treatment did not fully meet the requirements of pharmacy. When the course of study was over training was not at an end. In a sense it was here that real training began. An attempt to prosecute "original research" would amply reward the worker in teaching him his own limitations and in leading him to know himself, while at the same time it might add something to our knowledge of natural things.

UNIVERSITY OF BIRMINGHAM.—The opening of this session marks the attainment of the majority of the University, which was founded in 1900 from the pre-existing Mason University College. On Oct. 7th a conversazione, held in the University buildings, was attended by a very large number of members of the University and its friends. All the departments were thrown open to inspection and many interesting exhibitions and experiments were shown. On Sunday, Oct. 9th, the annual service was held in the Great Hall at Edgbaston to mark the inauguration of the new session.

STATE CARE OF MENTAL DISORDER.

ANNUAL REPORT OF THE BOARD OF CONTROL (LUNACY AND MENTAL DEFICIENCY) FOR 1920.

THE Board of Control for England and Wales must be one of the most harassed of Government departments. On Jan. 1st, 1921, there were 120,344 notified insane under care; each member has about 10,000 mentally infirm patients to supervise (provided all the members take an equal share in the work). The nine visiting members must each see about 13,000 annually, whereas in Scotland the proportion of patients to each Commissioner appears from the Seventh Report of the Scottish Board of Control to be less than 3000.

The Commissioners and their Responsibilities.

The work of the Commissioners involves the examination of all certificates so as to be sure that the law is complied with in every case. Each of these patients has a right of appeal, and when claims for discharge cannot be entertained there is often aroused a feeling of resentment which later finds its expression in letters to the papers and occasionally in vindictive attacks. Although personal violence is rare, aggrieved ex-patients lose no opportunity of creating ill-feeling. The Board of Control is, therefore, always up against an accumulation of grievances and complaints which create prejudice and ill-will. This is not counteracted by a corresponding show of gratitude, as patients do not attribute their recovery to the Board. It might be said that in this respect the Commissioners are like magistrates and judges, but there is the difference that in one case there is a public inquiry and the accused has counsel to defend him, whereas no such opportunity is given to the patient complaining of his detention. We do not suggest that patients are wrongly detained or that proper care is not taken, but merely that the prejudice which exists might be mollified if some different procedure were adopted when complaints of detention were made. In Dr. Montague Lomax's book there is a significant passage which describes the visit of the Commissioners and the supercilious air of the medical superintendent who took them round. The window-dressing which preceded the visit is described at length, and so it would seem that in this asylum, at any rate, care was taken to make a good impression. If typical, this seems to indicate a wrong state of affairs. If the Commissioners are merely inspectors and the chief medical officer on the defensive the visit can do little good. The association of legal and medical commissioners may be unfortunate. It is difficult for a barrister to take the place of a consulting physician in involved medical cases. In 1848, when the Commissioners were first appointed, there were terrible abuses to be eradicated, and presumably it was necessary to make minute inspection of rooms to see whether patients were concealed, but surely all this is changed, and if there are any abuses those responsible for the management of the institution are just as anxious for their removal as the Government visitors. This year Part II. of the Blue-book, which contains extracts from the Visiting Commissioners reports, has not been published.

Provision for Incipient Mental Disease.

A report by a Government body is hardly the place to look for defects in the Act of Parliament which it is required to administer. The necessity for change is admitted, and the Board again expresses its approval of a change in the law, in order to give improved facilities for treatment of early and incipient cases of insanity. The hope is expressed that a comprehensive measure on the subject will again be submitted to Parliament at an early date. [The Ministry of Health (Miscellaneous Provisions Bill, Clause 10) was refused a second reading in the House of Lords on Dec. 14th.] One aspect of this difficult subject seems so clear and obvious that it is strange and the newspapers frequently contain accounts of serious, and in some cases horrible, crimes which have been committed by persons of this class. At the same time the medical man who is called upon to examine a person guilty of persistent misconduct or crime must bear in mind that it does not of necessity follow that he is a moral imbecile. As Dr. Tredgold points out, continuous misconduct may result from a disorder of these controlling functions of mind, a not infrequent event during the period of adolescence; it may also result from their delayed development, and this may be a consequence either of some individual peculiarity or of faulty training and surroundings. In the moral imbecile it is neither a question of disorder nor delay, but of a fundamental and innate defect of mind in consequence of which the individual remains permanently incapable of adapting his conduct to the requirements of the community.

POINTS IN SANATORIUM CONSTRUCTION.

A WELL-ATTENDED general meeting of the Society of Superintendents of Tuberculosis Institutions was held at 122, Harley-street, W., on Oct. 3rd. After the representatives of the society to the International Conference on Tuberculosis had made their reports, Mr. Edwin T. Hall, F.R.I.B.A., delivered an address on Some Points in Sanatorium Construction, illustrated with lantern slides, in which he emphasised the necessity of close coöperation between the medical officer and the architect, as the latter was apt to overlook points bearing on the administration of institutions for the tuberculous. Mr. Hall expressed his general agreement with Committee Report No. 7 of the Society, which dealt with the construction and equipment of tuberculosis institutions, and went on to state some personal opinions on the subject. He considered that every room should receive some sunlight during the course of the day, and therefore favoured south, south-west, or south-east aspects. No ward or pavilion should overlook another; rooms might contain one bed or more, up to the number of eight. Dining and recreation rooms were better kept separate; if either apartment had to serve as chapel it was advisable to have the altar well screened off. The nursing block should have heating apparatus ready for use, and a small isolation block was desirable; covered ways of communication were practically indispensable in this climate. The rooms of the nursing staff should face away from the rest of the sanatorium buildings.

THE INTERNATIONAL ASPECTS OF ALCOHOLISM.

THE ninth Norman Kerr memorial lecture was delivered on Tuesday last by Sir Arthur Newsholme, late Principal Medical Officer to the Local Government Board. This lecture, it will be remembered, was established in 1884 in honour of a great temperance worker and in connexion with the Society for the Study of Inebriety; and Sir Arthur Newsholme, who has only recently returned from his duties in the United States, directed especial attention, in discussing the international aspects of alcoholism, to the question of prohibition in America. The great social revolution in America he attributed partly to organised propaganda against the abuses in drinking saloons—these seriously reflected upon the conduct of municipal politics, partly to temperance teaching in the elementary schools, partly to a national desire to improve industrial efficiency, and partly to strongly expressed opinion on the part of the medical profession in America. He alluded also to one other factor—namely, the occurrence of bestial attacks upon women in certain districts by negroes inflamed by drink.

The results of the first year of national prohibition in America are admittedly only partial, smuggling and illicit stills having some small counter-effect, while we can easily learn from newspaper reports that large secret stores still exist. But, according to Sir Arthur Newsholme, the vast majority of the American population can no longer obtain alcohol; the law and the cost preclude the indulgence, with the result that large sums of money have been diverted to the purchase of better clothing, while preventive work can take the place of rescue work in populous centres, and admissions to hospitals for alcoholism show remarkable decline. Defending the action of the United States from the accusation of being arbitrary or undemocratic, the lecturer pointed out that in all civilised countries there are many examples of enactments which diminish freedom of action for the many, but which are devised for the protection of the few with the sanction of the community. In such instances, while he admitted that moral and voluntary procedure would always be preferable to compulsion, he urged that moral suasion acts slowly even on minorities, during which time the innocent suffer for the lapses of the weak. He found the suggestion that prohibition might exercise a sinister influence on the moral fibre of the American population by encouraging "prohibition cranks" fantastic. As in a democratically governed country the sale of an article for consumption can never be prohibited unless its consumption can be shown to the satisfaction of the majority to be mischievous the case in favour of enforcement of prohibition in America is rendered strong by popular acquiescence. After all, democratic government is a government by majorities, and where compulsion seems to be a necessary element for success, that success can only be permanent with the consent of the governed.

THE ÆTIOLOGY OF TYPHOID FEVER.

DR. W. H. Hamer in his presidential address to the metropolitan branch of the Society of Medical Officers of Health last week, raised some interesting points. Fifty years ago, he said, it was the fashion to ascribe typhoid fever to faulty drains; later river water-supplies and polluted milk were held responsible. It was recognised 70 years ago that typhoid excreta were the source of danger, but not fresh evacuations, direct case-to-case infection not being admitted. Murchison countenanced de novo origin, and Pettenkofer ascribed importance to earth temperature and ground water-levels. In the nineties were discovered (1) Eberth's bacillus, and (2) that typhoid could be communicated by shell-fish, with the result that epidemiology was divided into "contagionists" (following Koch) and "localists" (following Pettenkofer), the former quickly getting the upper hand. Bulstrode's great oyster report was published in 1896, and that on other shell-fish in 1911, but the shell-fish discovery had not the same wide reception as Eberth's discovery. In 1900 fish outbreaks occurred in London, and in the next ten years the importance of estuarial pollution was increasingly realised. Dr. Hamer attributed the disappearance in London of the autumnal rise of typhoid in 1907, and from 1912 onwards, partly to the abandonment by the East Coast fishing companies of certain nurseries of small flat fish. A similar change, observed in 1914 in Manchester, was attributed by Dr. J. Niven to improvement in the quality of mussels. Meanwhile, those advocating the contagion hypothesis were in difficulties. Sewer men did not contract typhoid fever; convincing examples of direct case-to-case infection were hard to find, and could be explained by persistence of the original cause. The supporters of the contagion theory had to back on unrecognised cases and healthy Dr. Hamer pointed out that the bacteriolo typhoid had, in recent years, become the present time, therefore, was appropriate review of the position. Human testimony often fallacious, and the credibility of a varied in an extremely complicated way acc- to the subject. Sensations relevant to the in- had necessarily been filtered, as it were, t the medium of the witness's interest. N was more obscure than the process by wh

In a speech delivered after the distribution of certificates of honour, prizes, and medals, the Minister said that he was glad to see a number of women graduates as there was a great demand for women doctors and health visitors throughout the Presidency; all women workers were needed to combat the appalling rate of infant mortality. The Government were considering the establishment of a new college in Madras or in the *mofussil.* Referring to the prospects in the medical services he said these had been recently improved. The pay of both assistant surgeons and sub-assistant surgeons had been increased, and this should be a real source of encouragement to them. The more students were passed out of the college the better assured would be improvement in public health. He asked them not to think of non-coöperation; if they coöperated they could extend medical relief to the remotest corners of the Presidency. Mr. Gandhi would advise them to boycott Government medical institutions on the ground that the medical relief given was different from what the people desired. If they adopted Mr. Gandhi's advice, the world, for them, would come to an end.

The Surgeon-General (Lieut.-Colonel T. H. Symons), referring in the course of his speech to recent criticisms in the newspapers—especially those relating to stipends—said that these criticisms expressed only half-truths. When a student received a stipend, the Government put the student through his medical course, and asked the student in return to sign a bond to serve for a term of years in the department. When he got a lucrative practice, he was at liberty to repay the stipend. There was no indenture in this. Nor did the students come under martial law, as had been announced. These mis-statements might create an impression in the minds of the readers that Government did not deal fairly with the students. On the contrary, but for Government help, there was no denying that many of them could not possibly enter the profession at all. Medical training in India was easily bought, easily paid for, and never appreciated. In England it was very different.

Madras, Sept. 14th.

LONDON MEDICAL EXHIBITION.

THE eleventh London Medical Exhibition held at the Central Hall, Westminster, from Oct. 3rd to the 7th provided an almost bewildering display of fine chemicals, foods, medical and surgical instruments, and apparatus. The general practitioner and the specialist alike could find exhibits of absorbing interest, and every stall was surrounded by eager medical men and women anxious to see and hear about all the newest and up-to-date in armamentarium. Nor were physical needs forgotten, for excellent teas and cigarettes were provided free in the tea-room set aside for members of the profession and their friends.

In only one respect we think could the Exhibition have been improved: there seemed to be no definite plan in the arrangement of the stalls. In these days it is rare to find any medical man who has not some pet specialty, and busy people who could only spare an hour or two necessarily missed much that would have interested them. On future occasions it would be an improvement to have exhibits of a like nature grouped together.

Surgical, Medical, and Publishers' Exhibits.

It would be impossible in a short space to describe even a small proportion of the exhibits in detail.

Meyer and Phelps showed a new gag for use during tonsil operations, the new Laforce hæmostatic guillotine, Dr. Irwin Moore's direct vision œsophagoscope with distal lighting, and Gillies's modification of Kilner's retractor for Thiersch skin-grafting amongst a profusion of surgical instruments of all descriptions.

H. E. Curtis and Son exhibited their well-known abdominal support; a new modification made of celluloid with washable [illegible] seems very practical.

E. A. Brook Williams stall was replete with the latest text-books and monographs on medical subjects.

Allen and Hanburys, Ltd., were showing, amongst other surgical instruments, Thomson Walker's bladder retractor with Clifford Merson's lighting attachment and Swift Joly's direct vision posterior urethroscope. London Hospital catgut and Soutar's needle also attracted much attention.

The Tintometer, Ltd., showed ingenious colour scale apparatus and Dr. George Oliver's hæmoglobinometer.

Hawksley and Sons showed scientific, physiological and acoustic instruments of every description.

Various types of medical atomisers and sprays manufactured by De Vilbiss Co., Ltd., were on exhibition on Stand 26.

Charles Hearson and Co., Ltd., showed, amongst other exhibits, apparatus for small laboratories suitable for medical men doing bacteriological and venereal work.

Baillière, Tindall and Cox displayed a selection of medical and surgical works including the English edition of Doyen's Surgical Therapeutics and Operative Technique.

The latest X ray apparatus both for radiography and therapeutics was to be found amongst the exhibits of X Rays, Ltd. Here we saw also a number of single flash bismuth meal radiograms by a London radiologist, printed on Wellington X ray paper. The clearness and brilliancy of these prints renders them particularly suitable for diagnostic purposes; and the Wellington X ray plate on account of its great speed is specially adapted for single flash radiography.

Jaeger underwear and outer wear was exhibited on Stand 51.

The Domen Belt Co. exhibited a variety of belts for pregnancy, umbilical hernia, floating kidney, and other purposes.

Stronglite arms made by Cory and Grundy proved very interesting and were demonstrated to great advantage by an armless man, who, we were informed, had only within the last day or two worn the arm.

The new Bard-Parker knife, a Record syringe for export with replaceable barrels, the obstetric helper, and Barton's sphygmomanometer were to be seen at the Surgical Manufacturing Co.'s stall. The same firm also showed their "Excel" portable operating table, which folds down into a small space and weighs about 27 pounds.

Various appliances for deformities of the feet were shown by the Scholl Manufacturing Company.

At the Gas Light and Coke Company's stall was demonstrated the new economy gas flue, which has the triple advantages of reducing building construction, improving ventilation, and removing unhygienic corners.

H. K. Lewis and Co. showed not only a number of recent standard works but also a special selection of medical stationery.

The Sanborn Company exhibited a number of pieces of apparatus, amongst which was Benedict's metabolism apparatus for determining basal metabolism.

The Oxford Medical Publications stall was crowded with their well-known publications in medical, surgical, and general science.

A number of electrical aids for the deaf of various pitches were exhibited by W. H. Pettifer, as well as trumpets, tubes, and sound collectors.

Leoline Edwards, of Twickenham, exhibited an electric lamp heater which could be used for various other purposes.

Stanley Phillips, booksellers, were selling a selection of the latest medical books for post-graduate students.

Some interesting examples of the Eastman Dupli-Tized X Ray Film were shown by Kodak, Ltd. Amongst these we noticed a negative showing visible gall-stones.

The products of Carl Zeiss, Jena, were demonstrated by J. W. Atha and Co., sole agents for the British Empire. Every form of optical instrument, from microscopes to glass artificial eyes, was on view here.

An excellent electrical steriliser provided with a safety fuse, known as the Wilmot-Castle, was shown by De Trey and Co., who also exhibited various dental apparatus.

The Aurorascope Co., Ltd., showed their pocket outfit, by means of which the ear, mouth, nose and throat can be examined without the use of a dark room.

The Sterling Corporation, Ltd., had on view portable high-frequency violet ray generators and other electrical specialties.

Non-inflammable celluloid known as pexuloid, suitable for orthopædic appliances, was exhibited by Beckett and Bird, Ltd., one of whose factories is at the Ministry of Pensions special hospital at Shepherd's Bush.

A. G. Sheldon and Co.'s exhibit consisted of sterilised surgical dressings, the supply of which at any hour of the night or day is this firm's specialty.

The Pringle and Kirk mechanical arm and safety leg, fitted with an automatic knee-lock, were exhibited by the "P. K. Arm, Ltd."

Arnold and Son's exhibit took the form of a complete operating theatre in which the Royal operating table was conspicuous.

OPENING OF THE SESSION AT THE MEDICAL SCHOOLS.

THE DRAMATIC SIDE OF SURGERY.

THE introductory address at the opening of the winter session of the Middlesex Hospital Medical School was delivered by Mr. **GORDON TAYLOR** at the Scala Theatre on Oct. 4th. He chose as his subject, "The Dramatic Side of Surgery." After referring to some of the spectacular episodes of civil surgical practice, Mr. Gordon Taylor went on to describe in detail the brilliant achievements of surgeons during the war. The aeroplane proved of great value as a means of rapid transit, and in this connexion Mr. Gordon Taylor said: "The French conceived the idea of having aerial ambulances in order to quickly convey the wounded—especially the gunshot wounds of abdomen and chest—from the 'aid-posts' just behind the firing line to hospitals well equipped for dealing with such cases. Nemirovsky and Tilmant organised an aeroplane which they named the 'aerochir,' on the analogy of the 'autochir,' to carry a pilot, a surgeon, and a radiographer who could act as a surgical assistant. This 'aerochir' carried X ray apparatus, steriliser, instruments, dressings, &c. By its means it was thought (1) that surgical aid could be brought to the patient quickly; (2) the surgeon could be brought to the patient, and not the patient to the surgeon, and the patient thereby saved a journey before receiving surgical aid; (3) it would not increase traffic on roads used for purely military purposes; (4) formations of aeroplanes could rapidly transfer surgeons from one part of the fighting line to another."

Similar methods were also in use, said the lecturer, in the British army. The surroundings in which surgical work was accomplished might lend the dramatic touch; thus, said Mr. Gordon Taylor: "It is difficult to imagine a more dramatic environment for surgery than the dug-out which Basil Hughes, of Bradford, built in a communication trench when he was a regimental medical officer; to this a wounded man could be brought in four or five minutes after being hit. Six abdominal cases associated with severe hæmorrhage were operated upon by Hughes here, and two recovered; these were men, who, in his opinion, would never have lived to see a casualty clearing station." Mr. Gordon Taylor recorded several instances of soldiers who received penetrating abdominal wounds on two occasions and recovered from each, and he also considered wounds involving two or more of the body cavities. With regard to abdominal wounds Mr. Gordon Taylor said: "The results of abdominal wounds operated upon by average surgeons in the war showed a recovery rate of about 50 per cent., if these cases were selected with some care; naturally the recovery rate was lower where the surgeon exercised less discretion in his choice of cases, or was willing to extend the benefits of surgery to patients however desperate their condition. Douglas Taylor and Geoffrey Marshall's 74 per cent. recovery rate in one series of 101 cases was the most striking ever obtained. The statistics of abdomino-thoracic wounds in the earlier years of the war were gloomy reading, but out of 207 cases of this type operated upon in the Fourth Army in 1918 which I collected and analysed, 66·6 per cent. got well." Blood transfusion was now becoming an everyday operation, and Mr. Gordon Taylor related cases that had occurred in his practice, in which transfusion had saved the patient's life, and also referred to the difficulty sometimes experienced in civil hospital practice in obtaining a suitable donor. Amongst other dramatic operations performed he mentioned the successful removal of a rifle bullet from the intrapericardial portion of the inferior vena cava by Pierre Duval, and the resection of large portions of the intestines in cases of abdominal wounds.

The Middlesex Hospital, said the lecturer, was intimately connected with the history of calculus surgery. In 1880 Sir Henry Morris was the first to perform nephrolithotomy, in 1891 Sir John Bland-Sutton carried out the second successful choledochotomy in this country, and in 1891 Sir Alfred Pearce Gould first removed a stone from the pancreas. The dramatic and spectacular operation of lithotomy was now replaced, wherever possible, by litholapaxy. In conclusion Mr. Gordon Taylor said: "Time fails me to speak of many other dramatic operations performed during the war, nor do I desire to harrow your feelings with Grand Guignol tales. I could speak of an air pilot with a severely damaged heart bringing his aeroplane safe to the ground, of soldiers walking back with protruding bowel to their own lines to recover with the aid of surgery, of occasional bayonet wounds involving even the bowel successfully treated, and we many of us have successfully extracted curious missiles from the wound of the injured soldier—pennies, francs, buttons, the finger of a comrade, and even fragments of the pages of the Continental *Daily Mail.*"

PROFESSIONAL TRAINING IN PHARMACY.

THE inaugural sessional address of the School of Pharmacy of the Pharmaceutical Society of Great Britain was delivered on Oct. 5th by Lieut.-Colonel Sir **DAVID PRAIN**, C.M.G., F.R.S., Director, Royal Botanic Gardens, Kew.

"On the occasion of the opening of a new session," said Sir David Prain, "one's thoughts naturally turn to the studies that lie before one. Between the preliminary assessment of knowledge gained at school and the qualifying examination on the completion of the professional studies three separate disciplines intervene as set out in the various suggested compulsory curricula: (1) A training in pure science; (2) a pupilage in pharmacy; and (3) a course of professional studies." Five years ago, the then president of the Pharmaceutical Society stated in an inaugural address that it had been the policy of the Society to reverse the order of the first two. Sir David Prain felt this to be an encouragement to himself, as during 16 years he had adopted a similar order in the training of student-gardeners. Proceeding to deal with professional training in general, he said that conflict between theory and practice was impossible. Even in cases where exponents of a craft seemed to accomplish their tasks without the conscious study of underlying principles, these principles still existed, and the most consummate master of practice could not fail to benefit by the study of principles.

In medicine practical pupilage was the method originally adopted. The necessity for a knowledge of underlying principles of chemistry, physics, and biology soon impressed itself upon the profession and a "course of professional studies" was instituted and expanded at the expense of pupilage until the latter disappeared. Medicine found that professional training gave better results than pupilage; but since such training did not afford the opportunity for education which pupilage gave, a preliminary training in pure science was prefixed to the professional studies when pupilage ceased. This policy interested the pharmacist because certain prominent men had advocated its adoption, in view of the fact that pupilage in pharmacy may ultimately disappear as it has done in medicine. While pupilage remained the present policy of the Society seemed preferable. When pharmacy had to devise a new policy she might study the example set by medicine with advantage.

Husbandry and pharmacy had their origin side by side. Husbandry aimed at the maintenance of health while the function of pharmacy was to relieve sickness. Neither of these crafts fulfilled its purpose completely, and medicine was invented as an art directed towards the prevention of disease and later to its cure. Finally medicine passed from the defensive to the offensive, and now attempts to abolish disease. The secondary object of medicine tions, this laxative must be in great favour at the present day, and it is of interest to notice the importance attached to the viscosity and specific gravity of the oil. The various makers of this preparation justly claim that their products are tasteless, but the objection of many patients is chiefly to the unpleasant oily sensation in the mouth caused by the pure oil and this physical characteristic is not likely to be overcome except by a judicious blending with other materials.

The results obtained in the many recent researches into vitamins are reflected in the exhibition by different firms of preparations which, it is claimed, contain the three essential food accessories.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Glasgow.

THE report of Dr. A. K. Chalmers for 1920 is full of interesting matter. The population of Glasgow is estimated at 1,115,230. The inhabited houses number 235,031. The unoccupied houses which in 1913 numbered 18,710 are now only 201, of which 120 are one-apartment and 72 two-apartment houses. The birth-rate has risen from 23·18 in 1919 to 29·26 in 1920. The death-rate in 1920 was 15·03; the infant mortality rate 106: the death-rate from phthisis 1·06; and from all forms of tuberculosis 1·46. A special feature of the report is the account by Dr. A. S. M. MacGregor of the small-pox outbreak which has been brought up to date, the outbreak having terminated in March, 1921. In all 578 cases were dealt with, of whom all, except three who died at home, were treated in hospital. Of the 578 cases, 429 had been vaccinated, 128 had not been vaccinated, and 21 were said to have been vaccinated but presented no evidence whatever of a scar and were classed as doubtful. The fatality rate per cent. among the "vaccinated" was 16·1, among the "unvaccinated" 36·7, and among the "doubtfuls" 42·9. Anti-vaccinators will no doubt comment on the facts that more vaccinated than unvaccinated were attacked and that the fatality rate was greater among the "said to have been vaccinated" than among the unvaccinated. Of the nine deaths among the "doubtfuls," or "said to have been vaccinated," one occurred at the age period 15–20, one at the age period 35–45, and the remaining seven at age periods over 45, so it may be said without fear of contradiction that the "doubtfuls" died at an age when the transient protection afforded by a vaccination so inefficient as to leave no scar must have long ago passed away. It is well recognised that the protection afforded by *infant vaccination is only temporary*, and its value in warding off both attack and death is well shown by the statistics for cases under 15 years of age. Thus 30 vaccinated children under 15 years of age were attacked and none of them died; while 112 unvaccinated children under 15 were attacked and 38 of them died. Since the Vaccination Act (Scotland), 1907, was passed the proportion of successfully vaccinated children has fallen from over 80 per cent. to about 50 per cent., and the percentage of conscientious objections has gradually risen to 27 per cent. At the beginning of 1920, Dr. MacGregor estimates, there were about 127,000 unvaccinated children under 15 in Glasgow. Dr. MacGregor further estimates that 449,000 persons are now adequately protected and that there is therefore plenty of material for a further severe outbreak among the remaining inadequately protected 60 per cent. of the population.

Dr. MacGregor considers it essential to have chicken-pox added to the list of notifiable diseases during a small-pox outbreak, such notification to be followed by verification of the diagnosis in certain cases. By this means 13 cases of small-pox notified as chicken-pox were discovered. Dr. MacGregor was much struck by the manner in which efforts to control the epidemic were defeated by the occurrence of "missed" cases, and gives ten examples of patients who moved about freely among the population and who were only diagnosed when they caused recognised cases among their immediate contacts. The percentage of vaccinated cases with a sparse eruption is given as 56·5 and of unvaccinated as 12·3. It would be interesting to hear what proportion of the missed cases were unvaccinated.

Dr. Chalmers draws attention to the utterly inadequate provision for surgical tuberculosis. As modern treatment gives such promising results, it is to be hoped that this omission on the part of Glasgow, may, before long, be made good.

The work of the venereal disease treatment centres continues to grow. The number of new cases who received indoor treatment was 826 and out-patient treatment 5739. The corresponding numbers in 1919 were 748 and 4976. The average attendances per new case was 13·8, compared with 9·5 in 1919. Dr. Chalmers says: "It is a common observation that comparatively few (patients) will attend clinics until they become non-infective, but cease whenever *pain or discomfort* is lessened." At the Broomielaw centre Dr. Chalmers estimates that roughly 61 per cent. of the patients are defaulters in this respect and the attendance at Broomielaw is declared to be as good as elsewhere. Nevertheless Dr. Chalmers does not think that the time is ripe for demanding legislative powers to compel patients to remain under treatment until medically discharged, as proposed by the Corporation of Liverpool. Dr. Chalmers refers to the disconcerting evidence supplied by the number of new cases.

No case of total blindness resulted from ophthalmia neonatorum during the year, although in ten children the sight of one eye was lost and in four impaired, as was also the sight of both eyes in two other children.

Northamptonshire.

The estimated population of the administrative county for 1920 was 215,968 for birth-rate and 215,777 for death-rate. The birth-rate was 22·74, as compared with 14·34 in 1918 and 14·52 in 1919. The death-rate was 11·09. The infant mortality rate was 59, the lowest ever recorded. In the urban districts of the county it was 63 and in the rural districts 56. The tuberculosis death-rate was 0·94. There was a marked increase in the tuberculosis death-rate in the county during the war years, but this has now disappeared.

Housing schemes have made considerable progress in spite of the "grossly high" rates prevailing in the building trade. Dr. C. E. Paget records with satisfaction that many of the districts have arranged for the regular veterinary inspection of dairy cattle. We note that very inadequate penalties have been inflicted for the watering of milk.

Dr. Olivier Muriset, the tuberculosis officer, reports that a new method of diagnosis by tuberculin is being tried at the dispensaries and also that an X-ray apparatus was purchased at the end of the year. *Twenty shelters are loaned out* by the county council. Much of the surgical tuberculosis work is done at the Northampton General Hospital. There is good coöperation between the tuberculosis officer, the district medical officers of health, and the school medical officers, and the medical practitioners use the dispensaries for consultant purposes.

Dr. Lila S. Greig submits a report on maternity and child welfare work. Collosol argentum is supplied to midwives deemed capable of using it. All the 27 notified cases of ophthalmia neonatorum made a good recovery. The number of still-births was only 1·5 per cent. of the live births in 1920 and 1·9 per cent. in 1919. Notification of artifical feeding is not yet properly observed by the midwives.

The percentage of infants breast-fed up to the end of the seventh month was 73·5 and has steadily increased from the year 1910, when the percentage was only 53·6. Dr. Greig attributes this satisfactory result in considerable measure to the distribution of free milk to nursing mothers. In order to diminish nothing has been done. There were in England on Jan. 1st, 1921, 94 county and borough asylums equipped and possessing a trained staff, and provided by the community for the express purpose of treating mental disease. Not one of these can receive a voluntary patient. If anyone feeling in danger of a breakdown applies for treatment, he can only be told to go away and get certified. Should he not be certifiable, he must keep away from the public mental hospital until he has got so bad that even a justice of the peace can see he is insane. Something is being done in this direction in the out-patient departments of one or two of the London hospitals and at Wakefield, and if the London County Council get the Maudsley Hospital into running order more might be done there, but these are mere drops in the ocean of what is required. The Commissioners in their report seem to confine themselves to things as they are. They would, we feel sure, disarm criticism and advance reforms by pointing out defects in the present system.

Training of Mental Nurses.—Inquiries into Alleged Abuse.

Nothing in the report is said of the training of the nurses or the labour it involves, nor is there any comment on the reduction of hours or the introduction and the working of the three-shift system in some asylums. The Board in this matter is in the position of trustee for the patients, and should express an opinion on agreements made between the asylums committee and the staff where they affect the welfare of the patient. They support and advise the nursing of male patients by female nurses in all suitable cases and when structural conditions permit of it.

An account of two inquiries into alleged abuses is given, the first into conditions at the Lancashire Asylum, Prestwich. The charges of ill-treatment and improper detention were made by a deputation headed by Mr. Ben Tillett, M.P. The charges were found to be without foundation. Only 11 patients made complaints which were not obviously due to their insanity, and even in these cases no substantial basis was found. The members of the deputation were invited to meet the Board and be present at the inquiry. Mr. Tillett pleaded urgent business elsewhere, and the others failed to turn up.

The second series of charges were made in "The Friend," and arose from statements made at a meeting of the Society of Friends by four conscientious objectors who served as attendants as alternative to war service. The Board admit that some of the charges were true, but point out that the complainants saw asylum life under abnormal conditions. Staffs were entirely inadequate and many members were totally unsuited for the work. Food was, of course, controlled. The Board deprecate any form of "correctional treatment" and urge its entire abolition.

The Effect of Economic Conditions on the Care of the Insane.

There is reason to fear that at the present time the insane are not as well looked after as they were before the war, but for this the Board cannot be held responsible. It is purely an economic question. The worker has asked for and obtained shorter hours and higher pay. The taxpayer grumbles, and the obvious ways of reducing expenses are smaller staffs and economies on food, and so the patients suffer. In referring to deficiency of diet it may be noted that the Board states: "Complaints of the quality, sameness, and cooking of the food and methods of serving it have been more frequent, and in some instances certainly justified. Whenever we have found this to be the case we have pressed for improvement; but it is a matter with regard to which we have found some of the visiting committees and their medical superintendents not as ready to adopt our suggestions as could be wished." The average weekly cost of maintenance for year ending March 31st, 1920, was in county asylums, £1 1s. 10¾*d.*; in borough, £1 3*s.* 9¾*d.*, excluding costs of repairs, additions, and alterations. This is an increase of 5*s.* 6¾*d.* in the previous year, and in six years of 100 per cent.

Prosecutions Undertaken by the Board.

Six prosecutions were undertaken by the Board. Five of these were against persons who had been employed in various asylums. In all cases convictions were obtained.

As is usual in law, offences against property were much more heavily punished than offences against the person. Two men were sentenced to six months' hard labour for stealing £8 8*s.* 6*d.* from an ex-Service patient. The magistrate characterised their conduct as outrageous. Four persons summoned for ill-treating patients got off with sentences of £3, £5 or six weeks, £5, and £5 or one month.

The statistics generally show a reversion to pre-war conditions. There is an increase in the number of certified cases, but this only occurs in county and borough asylums; in all others there is a decrease. The total number of deaths were 8504—3565 fewer than in 1919, and 11,011 fewer than in 1918. The average death-rate on daily average number of patients is 8·64 per cent. This is the lowest ever recorded; this, perhaps, is directly consequent upon the abnormally high death-rate in recent years.

Research Work.

Grants for research were made for the year ending March 31st, 1921, to the amount of £1700. This amount is divided among six workers in sums varying from £150 to £400 per annum. In a supplement to the report, a record is given of (*a*) Grant Aided Research Work. This contains an excellent account of an investigation in an outbreak of pellagra. (*b*) Scientific Research Work in Asylums in 1920. This includes an account of six investigations in various asylums. We know that this is not all the research work that has been done during 1920. Why, then, have these six only been selected? It is right that in all cases where a grant has been made an account should appear in the report, but it is disheartening to other workers that it should appear as if these accounts described all the scientific research at present proceeding. Much excellent and far-reaching work is being done elsewhere on such subjects as the endocrines, metabolism, and investigations in the ovaries and testes in dementia præcox.

The Report of the Board of Control may be had, price 1*s.* 6*d.*, from H.M. Stationery Office. Part II., which is not published for reasons of economy may be consulted at the Offices of the Board.

INDIA.

(FROM OUR OWN CORRESPONDENT.)

Madras Medical College: Prize Distribution.

THE Hon. Dewan Bahadur P. Ramarayaningar, Minister in charge of the Medical Department, presided at the eighty-sixth annual prize distribution to the students of the Medical College, held on August 10th in the College Library Hall. Colonel F. F. Elwes, principal of the college, read the annual report for the year 1920–21, which was a record of good work. The total number of students was 579, against 523 the previous year, and he announced that to accommodate this number the college had strained its resources to the utmost. He added that further increase in the number of admissions was impossible, unless great extensions were made to the present buildings, or unless a new medical college was built. The present college was originally opened for the training of military (assistant) surgeons, but now accommodates not only them and university students, but also the lady apothecary, sanitary inspectors, and pharmacy classes. He pointed out that in a modern medical college there is no place for such addenda.

to that end he spared no labour or personal sacrifice. Though so much of his time and thought was given to laboratory work and technique, he was not one for whom these latter become per se the sole preoccupation. My recollection of him is of one for whom the interest of the laboratory was ancillary to and simply enhanced his interest in practical medicine. He was a man of high ideals, and to know him well was to realise the more his integrity of purpose, and his generous nature and the essential kindness of his heart.

To his widow, a medical woman who has worked closely with him and has published jointly with him articles in our columns, we extend our sympathy in her great loss.

WILLIAM DOMETT STONE, M.D. ST. AND., F.R.C.S. ENG.

Dr. W. D. Stone, whose death in London on Oct. 1st we recorded briefly last week, was at one time an acknowledged authority on questions of public health, and he did much to educate public opinion in matters of hygiene and sanitation. Born in 1840, he received his medical education at Middlesex Hospital Medical School and qualified M.R.C.S. Eng. and L.S.A. in 1861, becoming M.D. of St. Andrews University in the following year. In 1865 he took the F.R.C.S. Eng. His early medical appointments included those of resident medical superintendent at the Munster House Asylum, Fulham, and of *surgeon-superintendent for the* Government Emigration Service. He also held the appointments of hon. physician to the Westminster General Dispensary, the Western General Dispensary, and the Finsbury Dispensary; and of surgeon to the St. Marylebone Dispensary. A great traveller, he visited many different parts of the world, and for his services in instituting an inquiry into the hygienic condition of the Mercantile Marine of Great Britain, Sweden, Russia, the United States of America, and other countries, the Council of the College of Physicians of Sweden conferred upon him, in 1872, its Honorary Membership. When, in 1865, THE LANCET appointed a commission to inquire into the state of workhouse hospitals he championed the cause of reform in the *Times* and did good work in bringing about an amelioration of the undesirable conditions which existed at that time in poor-law institutions. He pointed out that the education and general status of the masters was often inadequate to their position, and he urged that an alteration of the standard of requirements for the posts of master and matron should be the first step in the reform of poor-law infirmaries. Dr. Stone edited with ability for many years the Half-Yearly Abstract of the Medical Sciences, and was the author of an "Epitome of Therapeutics." Of late years, owing to failing health, he has lived in retirement, although always retaining a keen interest in current events.

ROBERT HALE TROTTER, M.D. VICT., M.B., CH.B. LEEDS, M.R.C.S. ENG., L.R.C.P. LOND.

Dr. Trotter, a well-known practitioner in Holmfirth, Huddersfield, died on Sept. 10th, aged only 48. The second son of the late Dr. Charles John Trotter, he came of a family which has been closely associated since the beginning of the last century with the life of Holmfirth, where he lived. *He* was educated at Huddersfield College and the University of Leeds, winning the gold medal of his year. He graduated M.B., Ch.B. with honours in 1895, and in the same year became M.R.C.S. Eng., L.R.C.P. Lond. He took the degree of M.D. in the Victoria University in 1901. Identifying himself with many of the public institutions of the neighbourhood of Holmfirth, Dr. Trotter took a special interest in the Holme Valley Memorial Hospital, which owed its inception mainly to his personal efforts. His first appointment was that of house surgeon to the General Infirmary, Leeds, and from 1896 to 1911 he was medical officer of health for Holmfirth, Honley, and Holme combined districts. Later, while in charge of the medical ward at Royds Hall, he was appointed *temporary Major* in the R.A.M.C. He contributed to our columns in 1918 a paper on the Treatment of Neurasthenic and Hysterical Cases in General Military Hospitals and another entitled "Observations upon Condition known as D.A.H."

At a memorial service held at the Parish Church Dr. H. W. Williams paid tribute to the abilities of Dr. Trotter, and Lieut.-Colonel W. L. W. Marshall writes that on the staff at the Huddersfield War Hospital Dr. Trotter proved "a most efficient officer, a loyal comrade, a true friend, and an able physician beloved by the sick and wounded under his care."

DEATH OF DR. FREDERICK WILLIAM HENRY PENFOLD.—Dr. F. W. H. Penfold, who died at his residence at Rainham, Kent, on Sept. 30th, in his 62nd year, received his medical education at Guy's Hospital, qualifying M.R.C.S. Eng. in 1884 and L.R.C.P. Edin. in 1891. He was district medical officer to the Milton Union and hon. physician for in-patients at St. Bartholomew's Hospital, Chatham.

THE LATE DR. GEORGE ROLPH RAINE.—Dr. G. R. Raine, who died at his residence in Victoria-road, Darlington, on Oct. 3rd, was the eldest son of the late Dr. G. W Raine, of Billericay, Essex, and received his medical education at Guy's Hospital, qualifying M.R.C.S. Eng. in 1866. He held appointments at Guy's Hospital and at the Staffordshire General Infirmary, graduating M.B. Lond. in 1867, becoming L.S.A. in 1868 and M.D. Lond. in 1879. At the time of his death Dr. Raine was hon. physician to the Darlington Hospital.

THE LATE DR. JOHN WILLIAMS JONES.—The death of Dr. J. W. Jones, of Whalley Range, Manchester, who recently retired from practice owing to ill-health, is reported from Prestatyn. Educated at Glasgow University, Dr. Jones qualified L.R.C.P., L.M., and L.R.C.S. Edin. in 1884. He took up practice at Middleton, and married a sister of the late Alderman J. W. Lees. Dr. Jones was medical officer and public vaccinator to the Second District of the Manchester Union, and a member of the Manchester Pathological Society.

THE LATE DR. HERBERT BURLAND.—Dr. Herbert Burland, who died recently at his residence in Wellingborough-road, Finedon, in his 58th year, studied medicine at the Victoria University and at the Royal Infirmary, Manchester. He qualified M.R.C.S. Eng., L.R.C.P. Lond. in 1888, and practised at Finedon for 33 years. He held several local appointments, being medical officer to the Cottage Homes, Burton Latimer, to the post office, and to the Finedon District of the Wellingborough Union, and also a certifying factory surgeon and referee to several assurance companies.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lieut.-Cdr. P. B. Wallis withdraws with gratuity.

The following appointments have been notified:—Surg. Comdrs. J. L. Barford to *Pembroke*, addl. (temp.); S. Roach to *Orion*; and R. W. Stanistreet to H.M. Dockyard, Chatham.

ROYAL ARMY MEDICAL CORPS.

Capt. E. F. W. Mackenzie to be temp. Maj. whilst specially empld. as D.A.D. of P.

The undermentioned Capts. are secd.:—D. W. Pailthorpe for service with the *Egyptian Army*. H. G. Monteith for service under the Colonial Office.

The undermentioned Capts. retire receiving a gratuity: W. W. MacNaught (granted the rank of Maj.) and Kenneth A. Maclean.

Temp. Capt. F. K. Kerr relinquishes the *actg. rank* of Lt.-Col.

Officers relinquishing their commns:—Temp. Majs. A. T. Todd and S. G. Bell (retain the rank of Maj.). Temp. Capts. J. B. T. Keswick and F. J. Waldmeier (retain the rank of Capt.).

ARMY DENTAL CORPS.

To be Lts., with the temp. rank of Capt. (but without the pay or allces. of that rank): Temp. Capt. T. Edwards, Dental Surg., from Spec. List; Temp. Capt. S. H. Woods, Dental Surg., from Gen. List.

More medical books, including a number of new works on surgery, pathology, and venereal diseases, were exhibited by Wm. Heinemann, Ltd.

John Bell and Croyden, Ltd., displayed their sterilised dressings in hermetically sealed patent drums, ready for immediate use for accouchements and surgical operations, and various ligature and suture materials.

A comprehensive selection of the latest designs in electro-medical apparatus, including the "Pleurostat" universal apparatus providing currents for galvanism, ionic medication, electrolysis, cautery, lights, sinusoidal current, and faradisation, were on view at the stall of the Cox-Cavendish Electrical Company, Ltd. The same firm make a special X ray plate, the "Impex," by means of which instantaneous radiography may be undertaken with a gas-filled tube.

The Engineering and Survey Company exhibited X ray apparatus and special furnaces for the dental profession.

Epidiascopes, microscopes, and photo-micrographic apparatus were shown by Ogilvie and Co.

D. J. Taunton, Ltd., had no less than five stands filled with hospital furniture.

Radiant heat appliances for the treatment of rheumatism and allied disorders, as well as fractures and skin affections, were explained to those interested at the stand of the Dowsing Radiant Heat Co., Ltd.

The British Thomson-Houston Company's stand was devoted chiefly to the Coolidge portable X ray outfit and tubes.

The commendable work of the Food Education Society became evident from a study of their publications on dietetics at Stand 147.

Hoskins's hospital beds and equipment were exhibited by Hoskins and Sewell, Ltd.

Scientific Supplies, Ltd., showed a selection of glass-ware for medical and scientific purposes.

FOOD AND DRUG SECTIONS.

Foods.

At the exhibit of "Glaxo," Osnaburgh-street, London, N.W.1, useful information is provided regarding this dried milk, which can be obtained with full, three-quarter, or half normal cream content and is prepared in such a manner that the original vitamins present are not destroyed. Messrs. Horlick, Slough, Bucks, display their Malted Milk as a powder and in the more convenient form of tablets, whilst a somewhat similar product is exhibited by Messrs. Thew, Hooker, and Gilbey under the name of Hooker's Malted Milk. Genatosan, Ltd., of Derby-road, Loughborough, exhibit a readily assimilable tonic food "Sanatogen," prepared by a combination of casein and organically combined phosphorus, and the Sanagen Co., 8, Kennington Park-road, provide a closely related preparation known as "San-a-gen," containing the vitamins of the milk from which it is prepared. Other specialties of this firm include "Sanagen" Dietetic Biscuits and "Sanagen" Notan Tea Tablets.

Of the preparations exhibited containing the three vitamins A, B, and C, "Roboleine," supplied from the factory of Oppenheimer, Son and Co., Queen Victoria-street, E.C., and "Vitmar" manufactured by Callard and Co., 74, Regent-street, W.1, may be referred to. "Maltine," a product derived from malted wheat, barley and oats, and possessing a high diastatic power, together with its various combinations with tonic, laxative, and other drugs, is shown by the Maltine Manufacturing Company, of 9, Holborn Viaduct. The use of liquid paraffin in combination with other substances for the purpose of rendering the oil palatable is exemplified in the preparation known as "Virolax," supplied by Virol, Limited, Old-street, London. This combined food and drug contains 40 per cent. of virol with which is emulsified 60 per cent. of paraffin, and is agreeable to most patients. Messrs. J. and J. Colman, Ltd., 108, Cannon-street, show cereal preparations for the feeding of infants and invalids, and their exhibit includes Colman's mustard, employed as a counter-irritant in addition to its dietetic uses, and Robinson's "Patent" Barley, Groats, and Waverley Oats. The Apollinaris Co., Ltd., Stratford-place, London, W.1, show their two well-known mineral waters, "Apollinaris," a naturally carbonated table water, and "Apenta," a saline beverage used in the treatment of liver and bowel disorders. A large number of natural mineral waters are on view at the stand of Ingram and Royle, Ltd., Belvedere-road, S.E. 1, including Vichy-Celestins, Contrexeville, Carlsbad, Hunyadi-Janos, &c., and salts derived from some of these waters in the solid form for convenience in use.

Drugs.

A new anæsthetic exhibited by Savory and Moore, Ltd., under the name of "Ethanesal" (see THE LANCET, June 4th, p. 1173) prepared from highly purified ether is claimed to be superior to the usual anæsthetic ether or chloroform, being less toxic and irritating and causing less vomiting and other unpleasant after-effects. At the attractive stand of Allen and Hanburys, Ltd., attention was directed to their numerous organo-therapeutic products, the results of research work conducted by the firm. Of these products "Polyglandin," a compound granular preparation, has been found of service in nervous disorders such as arise at the menopause. The British Organotherapy Company, 22, Golden-square, W.1, also exhibit a wide range of similar products practically embracing the whole of such substances used in modern medical treatment. Notable among the many products supplied by Howards and Sons, Ilford, London, are "Agotan" (phenyl cinchoninic acid) the internal administration of which leads to an increased elimination of uric acid, cincaine (isopropylhydrocupreine) a local anæsthetic of low toxicity, and "Optochin" (thylhydrocupreine) a specific for several bacterial infections of the eye. Fine chemicals, principally derivatives of salicylic and benzoic acids, are displayed by Menley and James, Ltd., 64, Hatton-garden, E.C., and their specialty "Iodex," a preparation containing free iodine together with various medicaments derived from it, is given a prominent place.

An interesting exhibit is that arranged by British Colloids, Ltd., 22, Chenies-street, W.C. 1, where, by means of an ultramicroscope, the Brownian activity of their various colloidal products might be observed. The "Collosols" contain various metals, sulphur, and iodine, and possess the advantages over the same substances in the usual form, of higher therapeutic activity, and uniformity of action. The pharmaceutical products, vaccines, test cases, and other medical necessities furnished by W. Martindale, 10, New Cavendish-street, W.1, are in too great variety to be individually mentioned, although reference should be made to the salts of the chaulmoogric acids. Attention may also be drawn to the Extra Pharmacopœia of Martindale and Westcott now in the seventeenth edition, a mine of information in matters connected with the pharmaceutical and medical professions. Similar variety is shown in the many fine chemicals and other preparations exhibited by Burroughs, Wellcome and Co. in the form of "tabloids," "soloids," and other products. "Moogral" consists of a mixture of esters derived from acids of the chaulmoogric acid series and is the result of researches prosecuted by the company since 1904. Good results in the treatment of leprosy have been attained by the use of this preparation. Hedley and Co., Harrow-road, E. 11, show their chief product, ethyl chloride, and apparatus for producing general and local anæsthesia by its means. This substance is also used in their "Dridustol" spraying compositions, which are prepared by dissolving various drugs in this solvent. The solution when sprayed upon the skin rapidly evaporates, leaving a fine even deposit of the drug upon the surface.

Several vendors of liquid paraffin and its preparations are to be found amongst the exhibitors, but the firms principally restricting their exhibits to this medicament are the Anglo-American Oil Company, Bevis Marks, E.C. 3, who furnish a colourless and tasteless standardised product known as "Nujol"; the Angier Chemical Co., Ltd., 86, Clerkenwell-road, E.C. 1, proprietors of Angier's Emulsion containing 33 per cent. of paraffin emulsified with glycerine and hypophosphites of calcium and soda; and The W. Browning Co., Ltd., Albert-street, N.W. 1, whose "Semprolin" is obtainable as the refined oil or in the form of emulsions in combination with various drugs. The emulsions generally have an advantage over the plain oil in that they are miscible with aqueous liquids without separation.

The preparations exhibited by The Hoffmann-La Roche Chemical Works, Idol-lane, E.C. 3, include "Omnopon" a water-soluble powder containing the total opium alkaloids either alone or in combination with scopolamine for use in obstetric work, and "Sedobrol," which when dissolved in hot water forms a palatable broth, the seasoning being effected by sodium bromide (the active constituent) in place of common salt. This method of administration may be employed in all cases in which bromides are indicated. To the student of physiology or bio-chemistry the exhibit on this stand of various proteins, such as casein, hæmoglobin, &c., together with specimens of the compounds produced by their hydrolysis, will prove of interest. "Perkenol," shown by C. Zimmerman and Co., St. Mary-at-Hill, E.C. 3, is a convenient and useful product, which when dissolved in water yields a neutral solution of hydrogen peroxide of definite strength. Parke, Davis and Co., Beak-street, W. 1, Oppenheimer, Son and Co., and The Anglo-French Drug Co., Gray's Inn-road, exhibit a miscellaneous and interesting collection of general medicaments, colloidal preparations, disinfectants, organic therapy products, and vaccines which it is unnecessary to particularise.

A survey of the drug and food sections failed to show any new features of outstanding interest, but in spite of the present unrest and depression in various industries the production of numerous remedial and nutrient preparations appears to be in a thriving condition. Judging from the number of exhibitors displaying liquid paraffin B.P. and its many combina-

SULFARSENOL IN THE TREATMENT OF CONGENITAL SYPHILIS.

To the Editor of The Lancet.

Sir,—The article by Dr. E. Crawford and Dr. G. B. Fleming in The Lancet of Oct. 1st ends with the following statement, which appears to convey an erroneous impression :—

> "On the other hand, the work of Harrison, White, and Mills seems to show that intramuscular injection of neosalvarsan or its substitutes is more efficacious in producing a negative W.R. than intravenous injection of these drugs. In these cases, however, a very much larger dose was given intramuscularly than intravenously, and they did not attempt to determine the relative efficacy of the various arsenical preparations they used."

Reference to the paper by White, Mills, and myself will show that it is incorrect to say that a very much larger dose was given intramuscularly than intravenously. The drug given intravenously was "606" and the average amount was 2·8 g. That given intramuscularly or deep subcutaneously was "914" and the average amount was 3·97 g., which is equivalent to 2·64 g. "606." This investigation was based on the assumption, generally acknowledged now to be true, that, in equivalent doses, intravenous injections of "606" give better therapeutic results than injections of "914" by the same route. The results showed that the subcutaneous method gave 12 per cent. more negative reactions in primary and secondary cases respectively and led me to believe that the subcutaneous method gives better therapeutic results than the intravenous.

I find some difficulty in accepting Drs. Crawford and Fleming's conclusions as to the comparative value of sulfarsenol subcutaneously and "kharsivan" intravenously, as the number of their cases (23 under one year and 12 over) is too small to justify any serological comparison, particularly in groups of cases the members of which vary so much as do infants ranging in age from a day to twelve months. Another variant is in respect of the amount of treatment administered. I am the less inclined to accept the authors' conclusions, as my own experience of sulfarsenol in adults so far leads me to believe that, given *subcutaneously* it affords better therapeutic results than "914" given *intravenously*. But I have not yet sufficient figures to prove this point conclusively and prefer to suspend final judgment until figures are published which are free from objection. Meantime it may be justifiable to say that I have so far been very pleased with my results, both clinical and serological, which appear to bear out the good opinion formed of sulfarsenol by such French authorities as Emery and Lévy-Bing.

I am, Sir, yours faithfully,
L. W. Harrison.
Eccleston-square, S.W., Oct. 9th, 1921.

THE DANGERS OF THE PUBLIC SWIMMING BATH.

To the Editor of The Lancet.

Sir,—Aural surgeons for a long time have recognised the "bathing ear," and that the infection passes up the Eustachian tube to the middle ear from the nasopharynx in the great majority of cases. The septic water gets into the nose and nasopharynx owing to mismanagement of the breathing, or to stress caused by remaining under water for too long a period, especially at a depth. It may also enter the nasal accessory sinuses. I was once bathing with a friend at Madeira when he remained under water for a long time and at a good depth in order to pick up a pebble from the bottom. When he reached the surface he was rather exhausted, and complained of great heaviness of his face and head: on putting the head down water poured from both sides of his nose, obviously from the antra, with immediate relief and fortunately without septic infection. Middle-ear infection occasionally follows rupture of the membrane, if the ear "lands" flat on the water when entering from a height; only a few weeks ago a young man ruptured his left membrane, in the inferior segment, in this way when using the water chute in one of the best and most exclusive swimming baths; the middle ear became septic, and he died of meningitis. I may mention that he himself had a soft sore on his penis at the time!—I am, Sir, yours faithfully,

Savile-row, W., Oct. 7th, 1921. Arthur H. Cheatle.

POST-WAR PROBLEMS.

To the Editor of The Lancet.

Sir,—Two questions: first, are participators in "inter-allied" medical congresses going to boycott also German methods of treatment—e.g., the Erlangen X ray treatment of cancer now introduced at the West London Hospital? Secondly, when will British medical men treat the responsibility for the late war as a subject worth serious study, instead of taking their opinions thereon from interested politicians, and half-educated but wholly unscrupulous newspaper proprietors? I am, Sir, yours faithfully,

Barnsley, Oct. 7th, 1921. W. C. Rivers.

PATHOLOGY OF INSANITY.

To the Editor of The Lancet.

Sir,—A few days ago the Bishop of Kensington presided at a conference of a Spiritual Healing Fellowship at Church House, Westminster. For an account of the proceedings I am indebted to the London daily papers. I quote from one of them :—

> "Dr. Montagu Lomax, whose book describing his experiences as physician in a lunatic asylum has recently created so much stir, spoke about the wide scope available for spiritual healing. Psycho-analysis he sweeps aside. Of merely material medical treatments he knows the futility. In spiritual forces against mental weakness he has profound belief. And then Dr. Lomax expressed a rather startling belief in demoniacal possession and reincarnation. 'While I believe that the ills men suffer are the consequences of their own misdeeds,' he said, 'I do not necessarily mean in their present existing life, but in a previous incarnation.' The Bishop's fine head became a little more covered by his hand, and his manner a little anxious at this pronouncement by Dr. Lomax!"

A quotation from a second London daily paper is as follows :—

> "A paper on Spiritual Healing in Relation to Mental Disease was read by Dr. Montagu Lomax, who said he believed that insanity was sometimes much more than uncontrolled riot of the subconscious mind. He believed that in many cases, especially those of epilepsy, acute mania and melancholia, the subconscious mind of the moment was not uncontrolled, but that it was controlled by an evil and obsessing discarnate entity."

Has Dr. Lomax been correctly reported?

I am, Sir, yours faithfully,
Oct. 5th, 1921. M. H.

THE DISAPPEARANCE OF OSCAR GRAY.

To the Editor of The Lancet.

Sir,—At the time of writing nothing has been heard as to the fate of Oscar Gray, a Rugby boy, 17 years of age, who was last seen by anyone who knew him at Liverpool-street Station a few days before he was due to return to school. As it may not unreasonably be suggested in such a case that a schoolboy may leave his home prompted by a love of adventure or through some other motive, and as Gray's parents are suffering acute distress and anxiety, the following facts may be stated pointing to loss of memory or mental derangement brought on by the concussion of a fall as being the responsible cause of his absence. In view of these the case may usefully attract the attention of medical men attached to Poor-law institutions and police surgeons.

On the morning of the boy's disappearance he was to travel up to London from his home in Essex with a friend of his parents, who had been on a visit to the family. From Liverpool-street Station he was to go to Victoria, leave his luggage in the cloak-room overlapping the experiment is to be tried for two years of allowing the Northamptonshire District Nursing Association to carry out the health visiting in one of the districts, under the direction of the county medical officer of health and the lady medical officer. The V.D. clinic at the Northampton General Hospital has been now equipped for bacteriological and pathological work by a generous benefactor and the Buckinghamshire County Council have joined in the scheme.

Tunbridge Wells.

The estimated population for 1920 was 35,795, the birth-rate 18·3, the death-rate 12·5, the infant mortality rate 62·5, and the tuberculosis death-rate 0·97. 14·5 per cent. of the deaths were due to cancer. One does not expect to find the best mortality statistics in Tunbridge Wells, as its reputation as a health resort doubtless induces many invalids to take up their residence there.

Dr. F. C. Linton mentions that the maternity and child welfare work needs both proper premises and an increased staff, and draws attention to the fact that 21 of the 41 infant deaths occurred in the first week of life. Nine fresh cases of malaria were notified during the year; Dr. Linton repeats his warning of last year that *Anopheles maculipennis* is to be found in Tunbridge Wells, and asks that insects killed on suspicion of being anophelines be brought to the health office for identification, in order that the distribution of this insect in the borough may be ascertained.

Obituary.

SIR WILLIAM ROE HOOPER, K.C.S.I., F.R.C.S.ENG.,

COLONEL, I.M.S.; HONORARY SURGEON TO THE KING.

AN announcement was made in THE LANCET last week of the death at Aldeburgh, Suffolk, of Sir William Roe Hooper, a distinguished member of the Indian Medical Service. He was an officer who left his mark in India, where he spent the greater part of his professional life, before recall home to take up the important position of President of the Medical Board of the India Office.

Sir William Hooper had reached the ripe age of 84, for he was born in the year of Queen Victoria's accession to the throne. He received his medical education at St. Bartholomew's Hospital, qualifying as a Member of the Royal College of Surgeons of England in 1858. He entered the Indian Medical Service and for more than 30 years discharged important duties in the North-West Provinces. After 11 years' service in the Gaol Department, as Superintendent of the Central Prisons of Allahabad and Benares, he was in 1874 placed in medical charge of the latter important station and district. In August, 1891, as a reward for long and approved service, he was transferred to the civil surgeoncy of Lucknow, where he not only earned the approval of the Government but gained the confidence and affection of all classes of the European and native communities. In 1881 he received the special thanks of the Viceroy for the work which he had discharged, and between 1878 and 1893 on eight separate occasions he was thanked by the Government of the North-West Provinces of Bengal for his work at the hospitals and institutions under his charge. In a service which contains a long list of men who have given protracted years of incessant toil to the improvement of social hygiene and sanitary conditions in the Indian Empire, few names better deserve prominent recognition by his countrymen at home and in India than that of Hooper.

For a period of about 18 months during 1887–88, while on furlough, he had served as a member of the Medical Board at the India Office, and his appointment to the presidency of the Board in succession to Sir Joseph Fayrer was not unexpected. He retired in 1904 after an extension of his services for two years.

Among other offices which he held, all in direct connexion with his official work at the Board, he was an ex-officio member of the Senate of the Army Medical School, Netley, a representative of the India Office on the Committee to inquire into the organisation of the Army Medical Service appointed in 1901, a member of the Advisory Board for Army Medical Services, and of the Army Sanitary Committee. He also sat on the committee which prepared the new edition of the Nomenclature of Diseases, published under the ægis of the Royal College of Physicians of London. In 1897, while he was a member of the Council of the Lister Institute of Preventive Medicine, he received the C.S.I., and in 1903 was promoted to a Knight Commandership of this Order. In the following year he was gazetted honorary surgeon to the King.

Sir William Hooper married in 1859 Lucy, daughter of the late Mr. Henry Benson Cox, whom he survived. A son, Dr. John William Dunbar Hooper, is a gynæcologist practising in Melbourne.

ALBERT SIDNEY FRANKAU LEYTON, M.D., SC.D. CAMB., F.R.C.P. LOND., D.P.H.VICT.,

DIRECTOR OF THE CLINICAL LABORATORY, ADDENBROOKE'S HOSPITAL; LATE PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LEEDS.

Albert Sidney Frankau Leyton, who died at his residence, Great Shelford, Cambridge, on Sept. 21st, at the age of 52, was born in London, the son of Joseph Grünbaum. He was educated at the City of London School, at St. Thomas's Hospital, and at Gonville and Caius College, Cambridge, where he graduated M.A. in 1895, proceeding to the M.D. degree two years later, and to the Sc.D. in 1913. He completed an arduous and successful course of study by work on the Continent, notably in Vienna. A year after graduating at Cambridge he became a Member of the Royal College of Physicians of London, and later obtained the Diploma in Public Health at the Victoria University of Manchester. For a time he was assistant physician to the Liverpool Hospital for Consumption, and subsequently became lecturer on experimental medicine at the University of Liverpool. In 1903, having in the meantime been elected F.R.C.P., he was appointed director of the cancer research undertaken in that city. He delivered the Goulstonian lectures of the Royal College of Physicians of London in 1903, taking for his subject the Theories of Immunity and their Clinical Application. The lectures were published in THE LANCET at the time of their delivery, and were recognised as a clear and useful guide to a whole section of pathology that was quite new to many clinical workers. For a time he was professor of pathology in the University of Leeds.

Dr. Leyton was a man of versatile capacity and wide interest in research, and in Vienna in 1896 he did a remarkable piece of work, for he clearly forestalled Widal in devising the agglutination test in typhoid fever. Leyton, however, delayed publication until he had had an opportunity of confirming his results, and meanwhile Widal published an account of the test from independent investigations.

Prof. C. S. Sherrington, with whom Leyton had worked at St. Thomas's Hospital on cerebral physiology, writes as follows:—

> As one who knew Prof. Leyton well and was intimately associated with him in some of the work which he did, may I add a word of tribute to his memory? None who had close contact with him could fail to be impressed by features of his thought and character which make his relatively early death an untimely loss to scientific medicine. He combined in rare measure enthusiasm for research with a critical, and indeed, highly self-critical, attitude of mind. An earnest of his power of achievement was seen in his discovery of the agglutination reaction as a help to typhoid diagnosis, a discovery fraught with such high and still unexhausted consequences. Widely read and proficient, he was ever on the alert to take avail of means from the progress of collateral science for the immediate profit of medicine itself. He had imagination and at the same time no man endeavoured more sincerely than he to control theoretical suppositions by observational data. The advance of practical medicine was with him a passion; in his devotion

University of Sheffield Post-graduate Course.—A post-graduate course of lectures and demonstrations will be held in the Sheffield hospitals during the ensuing three months. Details will be found in our Medical Diary.

Royal Society of Tropical Medicine and Hygiene.—The opening meeting of the session will be held at 11, *Chandos-street, Cavendish-square, London, W.*, on Thursday, Oct. 20th, at 8.45 P.M. (demonstrations at 7.45 P.M.). The presidential address entitled "Life Insurance in the Tropics" will be delivered by Sir James Cantlie.

University of Manchester.—The congested conditions of laboratories and class-rooms seem likely to be maintained during the present term. Last year the total number of students was 3100, of whom 754 were in the Faculty of Medicine. In 1914 there were about 300 medical students, and in all probability this Faculty will have to supply teaching to about 700 students—men and women. A considerable number of ex-Service men are taking courses in pharmacy to fit themselves as dispensers. Mr. Arthur Burgess has succeeded Sir William Thorburn in the Chair of Clinical Surgery, and the Chair of Clinical Medicine, formerly held by Prof. Reynolds, is now held by Dr. Albert Ramsbottom. Prof. Donald has resigned the Chair of Obstetrics and Gynæcology, and is succeeded by Dr. W. E. Fothergill. The Council has created a new Chair of Clinical Obstetrics and Gynæcology, to which Prof. Donald has been appointed.—Entrance scholarships in Medicine have been awarded to Mr. William Brockbank, B.A., and Mr. C. N. H. Long, B.Sc. The Sir Clement Royds Memorial Scholarship in Chemistry has been awarded to J. F. Wilkinson, B.Sc., who will undertake research work in organic chemistry.

University of Oxford.—Mr. Edward George Tandy Liddell, M.A., B.M., of Trinity College, Oxford, has been elected to a non-official Fellowship for Research in Physiology. Mr. Liddell took a first class in physiology in 1918, and completed his medical course at St. Thomas's Hospital. Mr. Cyril Norman Hinshelwood, B.A., War Memorial Research Fellow (formerly scholar), of Balliol College, has been elected to an official Fellowship as Lecturer in Chemistry.

University of London.—A course of eight public lectures on Psychology and Psychotherapy will be delivered at King's College, Strand, on Tuesdays at 5.30 P.M., beginning Oct. 18th, by Dr. William Brown. Admission free, without ticket. The list of lectures appears in our advertisement columns.—Two courses of advanced Lectures in Physiology will be delivered during the first term of this session. Dr. C. Da Fano will give eight lectures on Histology of the Nervous System at King's College, Strand, London, W.C., at 4.30 P.M., on Wednesdays. The first lecture was delivered on Oct. 12th, and the next will be given on Oct. 19th. Dr. J. C. Drummond, D.Sc., will deliver eight lectures on Nutrition at University College, Gower-street, London, W.C., at 4.30 P.M., on Fridays, beginning to-day, Oct. 14th. Attendance at these courses is recognised in connexion with the B.Sc. (Honours) Degree in Physiology. The lectures are addressed to advanced students of the University and others interested in the subject. Admission free, without ticket.

Medico-Legal Society.—A meeting of this Society will be held at 11, Chandos-street, London, W., on Tuesday, Oct. 18th, at 8.30 P.M., when a paper will be read by Mr. W. Valentine Ball, barrister-at-law, on Incapacity for Work within the Meaning of the National Insurance Act, 1911.

Chadwick Public Lectures.—A lecture on "Plant Diseases and their Relation to Diseases in Man," will be delivered by Prof. V. H. Blackman, F.R.S., in the lecture room, Chelsea Physic Garden, Swan Walk, Royal Hospital-road, London, S.W., on Thursday, Oct. 20th, at 5.15 P.M., Sir William J. Collins presiding. The gardens will be on view before the lecture.

London Hospital Medical Society.—The programme for the ensuing session has now been issued. On Oct. 27th a Psycho-neurological evening will be held. On Nov. 10th Mr. T. P. Dunhill will read a paper, and on Nov. 24th Dr. J. H. Sequeira will speak. On Dec. 8th Dr. W. E. Dixon will read a paper on Physical Action of Drugs. In the second half of the session the meetings on Jan. 19th and March 2nd will be devoted to clinical subjects, and that on Feb. 16th to Gynæcology. On Feb. 2nd Dr. Henry Head will address the Society. The meetings are held on Wednesdays, and all old London Hospital students and their friends are invited to attend.

Medical Golfing Society.—A handicap singles competition on the knock-out system is shortly to be held. The entries close on Monday, Oct. 17th. Further particulars can be obtained from the Hon. Secretary, 36, Weymouth-street, London, W. (Telephone: Paddington 904.)

University of Aberdeen.—At a university court held on Sept. 27th it was announced that Miss Catherine Fyfe Grant, of Edinburgh, had bequeathed about £2250 to found a bursary in the Medical Faculty, to be known as the Grant Medical Bursary.

Old Students' Dinners.—*St. Bartholomew's Hospital.*—Old students met again for dinner in the Great Hall on Oct. 3rd after an interval of nine years. Mr. W. S. A. Griffith occupied the chair and took the opportunity to give a long overdue eulogy of Matthews Duncan and his work in raising obstetrics to its proper place in London. He proposed separately for the first time the toasts of "The Hospital" and "The Medical College" in view of the receipt of a Royal Charter by the latter. Sir William Lawrence, replying for the hospital, expressed his continued belief in the ability of spontaneous generosity to finance a great hospital. Mr. H. J. Waring, replying for the College, set out the constitution of the new Medical Council and its intentions in regard to further development of teaching units. Among many guests of distinction were the presidents of the Royal Colleges, both old Bartholomew's men, the vice-chancellors of Cambridge and London Universities, the secretary of the Medical Research Council, and the dean of Columbia University, New York. During the dinner it was announced that Lord Stanmore was succeeding Lord Sandhurst as treasurer of the hospital.

Charing Cross Hospital.—The annual dinner of the past and present students was held at Gatti's Restaurant on Oct. 5th. Sir James Galloway presided over a large gathering. After the loyal toasts had been duly honoured, "The Hospital and Medical School" was proposed by Mr. Norman Lake. A successful change was made from the usual custom of this toast being responded to by the Dean or other official: this year two students, Miss H. L. J. Wallace and Mr. W. H. Williams, replied. "The Guests" was proposed by Dr. J. M. H. MacLeod, the guest of the evening being Sir Frederick Mott, consulting physician to the hospital. In reply Principal Ernest Barker made a clever and humorous speech, while Sir Frederick Mott replied both in speech and song. Dr. W. C. Bosanquet proposed the health of the chairman, which was drunk with musical honours. During the evening, owing to the kindness of Sir Oswald Stoll, musical selections were given by artistes from the Coliseum.

St. Mary's Hospital Medical School.—The annual dinner was held at the Connaught Rooms on Oct. 3rd. The chair was taken by Dr. E. G. Graham Little, physician-dermatologist to the hospital, and 150 past and present students were present. In replying to the toast of "St. Mary's Hospital and the Medical School," Mr. A. R. Prideaux, the chairman of the board of management, alluded to the severe financial strain which was being felt by all the voluntary hospitals, but confessed himself an optimist who looked forward with confidence to the preservation of the voluntary system. Dr. C. M. Wilson, dean of the medical school, was in the pleasant position of being able to report most favourably on the events of the past year—the outstanding feature being the decision of the Board of Education to establish clinical units in medicine and surgery at St. Mary's. This he looked upon as a recognition by the educational authorities that St. Mary's was worthy of their support and assistance. The entry of new students had been well maintained, and the total number now studying at the school was larger than ever before. Among other interesting facts he pointed out that one-fourth of the total number of candidates for the Primary Fellowship examination from all the British schools were trained at St. Mary's. The chairman, in proposing the health of Sir William Willcox, on whom the honour of K.C.I.E. has been conferred during the past year, had as pleasant a task as could fall to the lot of any man, and on rising to reply Sir William Willcox received a remarkable ovation.

Middlesex Hospital Medical School.—Over 220 past and present students of the Middlesex Hospital assembled at the Trocadero Restaurant on Oct. 4th. Amongst those present were the Earl of Athlone, Sir John Bland-Sutton, Surgeon-Rear-Admiral Sir Percy Bassett-Smith, and Sir Edward Penton. Mr. Comyns Berkeley occupied the chair, and in proposing the toast of the Hospital and Medical School, gave an interesting account of their history since their foundation in two small houses in Windmill-street 146 years ago. The president also referred to the satisfactory condition of the medical school, in which over 600 students were working during the past year. Amongst the most important events of the year were mentioned the endowment of the Chair in Physiology, and the successful working of a scheme whereby the patients contributed

TERRITORIAL ARMY.

Capt. J. L. Hamilton to be Maj.

Capt. D. C. Maclachlan (late R.A.M.C.) to be Capt.

Capt. T. P. Cole resigns his commn. and is granted the rank of Maj.

Capts. J. M. Stalker and J. H. Chauncy resign their commns. and retain the rank of Capt.

Lt. R. Ward to be Capt.

Surg. Lt. W. J. C. Watt (late R.N.) to be Lt.

TERRITORIAL ARMY RESERVE.

Maj. C. N. Smith (T.A. Res.) to be Maj.

INDIAN MEDICAL SERVICE.

Capt. J. Findlay to be actg. Maj. while holding an appt. as Registrar of an Ind. Gen. Hosp.

Captains to be Majors: E. H. V. Hodge, A. MacD. Dick (Bt. Maj.), M. J. Holgate, T. L. Bomford, G. R. Lynn, L. H. L. Mackenzie (Bt. Maj.), W. A. M. Jack, Keshav Sadashiv Thakur, Mohamed Abdur Rahman (Bt. Maj.), H. R. B. Gibson (Bt. Maj.), M. A. Nicholson, R. F. D. MacGregor (Bt. Maj.), E. W. O'G. Kirwan, P. K. Gilroy.

DEATHS IN THE SERVICES.

On Oct. 9th, at Queen Alexandra's Military Hospital, Millbank, Lieut.-Col. Edmund Munkhouse Wilson, C.M.G., D.S.O., R.A.M.C., died in the 67th year of his age. He qualified L.R.C.P. Lond., M.R.C.S. Eng., in 1878 from St. George's Hospital, and as a civil surgeon saw active service in the Zulu war in the following year. For his services he received the medal with clasp. In 1881 he joined the Army Medical Department, serving in the Nile Expeditions of 1881–86, and was awarded the medal with clasp and the Khedive's Star. During the Gambia Expedition of 1891–92 he gained the medal and clasp, and in the Ashanti Expedition of 1895–96 was honourably mentioned, receiving the C.M.G. and star. As secretary to the Surgeon-General in the Sudan Expedition to Khartoum in 1898 he was mentioned in despatches, awarded the D.S.O., and English and Sudan medals. From 1899 for five years he was Deputy Assistant Director-General of the Army Medical Service at headquarters, and was afterwards employed at the R.A.M.C. Record Office, his services extending into the period of the late war. Lieut.-Col. Wilson, who was created a Knight of Grace of the Order of St. John in 1903, was president of the West London Medico-Chirurgical Society during 1918–19, and was at one time secretary of the R.A.M.C. Benevolent Society.

Major-General Peter Stephenson Turnbull, K.H.S., I.M.S. (retd.), died in Edinburgh on Oct. 7th, at the age of 85. He graduated M.D. at Glasgow in 1859, and joined the Indian Medical Service in the following year. He served in India under Lord Napier of Magdala in 1867–68. From 1882 to 1888 he was secretary to the P.M.O. of the Forces in Bombay, and from 1883 to 1885 also held the office of acting Inspector-General of Prisons in the Bombay Presidency. For five years he was Surgeon-General to the Governor of Bombay, and retired from the services in 1896, when he received the Good Service Pension. He was appointed hon. surgeon to the King in 1902.

Col. Sir William Roe Hooper, K.C.S.I., I.M.S. (retd.), Hon. Surgeon to the King, died on Sept. 29th, aged 84. He was president of the India Office Medical Board from 1895 to 1901, and had served in India from 1859 to 1895. He received the Companionship of the Star of India in 1897, and was promoted to Knight Commander of that Order in 1903.

Manchester Radium Institute: Opening Ceremony.—The Manchester and District Radium Institute, the first hospital of its kind in this country to be used exclusively for radium treatment, was opened by Lord Derby on Oct. 6th. The Institute, situated in Nelson-street, off Oxford-street, is in close proximity to the Royal Infirmary, the Royal Eye Hospital, and St. Mary's Hospital, and is the gift of Sir Edward and Lady Holt; in it will be concentrated most of the work formerly distributed amongst eight different institutions. During the first year of the Institute's existence, in 1915, there were over 2500 cases treated by radium; in 1920 the number rose to 8000; of these about two-thirds were treated for cancer in its various forms, but many of the cases had already reached an advanced stage before application was made for radium treatment. Sir Edward Holt remarked at the opening ceremony that, whatever doubts had been raised as to the curative value of radium in certain diseases, "the relief of suffering caused by its use is sufficient justification for our placing the Nelson House at the disposal of the Radium Committee." Experience at Manchester had shown that radium treatment might at least relieve the pain of cancer patients. A certain number of paying patients will be treated, and money received from this source will go to benefit the hospitals and poor people of Manchester and district.

Correspondence.

"Audi alteram partem."

INQUIRY INTO INSURANCE ACTS.

To the Editor of The Lancet.

Sir,—The Lancet of Oct. 8th contains a letter from the secretary of the Federation of Medical and Allied Societies, acting for his committee, in which a request is made to the Minister of Health "to consider the advisability of setting up an independent committee to take evidence in public, inquire into and report concerning the working of the National Health Insurance Acts." Among the signatories is the name of the secretary of the National Medical Union, acting for the council of that organisation. The Union consented to associate itself with the Federation *for this limited purpose only*. The wording of the preamble to this "request" is, however, capable of misconstruction as regards the National Medical Union, which, except in promoting this inquiry, is in no sense "coöperating in" the Federation in question. The Union is an independent body (in alliance with the Scottish Medical Guild), having its own policy, and founded in protest against the Medical Benefit Section of the National Insurance Acts.—I am, Sir, yours faithfully,

Alexander Blackhall-Morison,
Co-President (with Prof. Russell, of Edinburgh),
London, Oct. 8th. National Medical Union.

RESPIRATORY EFFICIENCY.

To the Editor of The Lancet.

Sir,—There is much to be said in favour of the doubt expressed in the leading article in your issue of Oct. 8th as to whether "respiratory movements as such"—i.e., mere pulmonary gymnastics—have any special virtue as regards the promotion of physical efficiency. It has to be remembered that the quite admirable sets of exercises devised respectively by Sir Herman Weber and Wing-Commander Martin Flack are not merely exercises in pulmonary gymnastics: they bring practically the entire muscular system into play, and it may well be questioned whether their undoubtedly good effect is not primarily and essentially due to this muscular factor, and whether an equally good result might not be achieved by a system of exercises in which the breathing was left to look after itself. As you point out in the article referred to, "athletes, horses, and dogs are trained by progressive muscular exercises, and the teaching of trainers has often been in advance of scientific knowledge, or more correctly stated, their knowledge based upon experience has not been regarded as scientific. We have a right to ask the physiologist what is the true basis for the so-called breathing exercises; there is no apparent reason for taking in more oxygen than the body needs, or for discharging an undue amount of carbon dioxide."

Naturally those recruits who were put through a course of Dr. Flack's exercises before entering upon the regulation course of physical training gave better ultimate results than those who did not enjoy this initial advantage; but it is at least questionable whether this second lot would not have done as well as the others if they had first been put through a carefully graduated course of muscular exercises having no special reference to the respiratory movements. Provided such exercises are suitably graded, the breathing and circulation tend to fall automatically into line. A question of interest in this connexion is the character of the breathing when the normal respiratory function of the lungs is interfered with—e.g., by disease of the heart or lungs. In my experience the breathing in such cases is instinctively modified in the way best suited to meet the difficulty. Curiously enough, the text-books have little or nothing to say on this point.—I am, Sir, yours faithfully,

Wimpole-street, W., Oct. 8th, 1921. Harry Campbell.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Oct. 18th.

GENERAL MEETING OF FELLOWS: at 5 P.M.
Ballot for Election to the Fellowship. (Names already circulated.)

MEETINGS OF SECTIONS.

Tuesday, Oct. 18th.

SECTION OF PATHOLOGY: at 8.30 P.M.
Dr. J. C. Mottram: Observations upon the Action of Radium and X rays upon the Mononuclear Leucocytes of the Blood.
Dr. W. Cramer and Dr. J. C. Mottram: Changes in Lymphoid Tissue after Exposure to X rays, and in Vitamin-Starved Animals.
Dr. J. A. Murray: Dissemination along Nerve-trunks in Tar-cancer.
Prof. S. G. Shattock: Dissemination along Nerve in Carcinoma of the Tongue.
Dr. A. Leitch: Casts of Tar-tumours in Rabbits.
Dr. C. C. Okell: The Sachs-Georgi Reaction in Syphilis (Dreyer's Technique and Bordet's Antigen).

Wednesday, Oct. 19th.

SECTION OF HISTORY OF MEDICINE: at 5 P.M.
Dr. Charles Singer (President): A Few Remarks on the Historical Work of the Past Year.
Dr. F. G. Chandler: The History of the Diagnosis and Treatment of Empyema Thoracis.

Thursday, Oct. 20th.

SECTION OF DERMATOLOGY: at 5 P.M. (Cases at 4.30 P.M.)
Cases:
Dr. H. C. Semon: (1) Psoriasis, treated by Danysz's Method (2 cases); (2) Tuberculosis Cutis.
Dr. George Pernet: (1) Band Sclerodermia of Leg in a Woman, showing Result of Treatment; (2) Epithelioma on Lupus Vulgaris in a Woman.
Other Cases will be shown.

Friday, Oct. 21st.

SECTION OF OTOLOGY: at 5 P.M. (Cases at 4.45 P.M.)
Presidential Address:
Dr. Logan Turner: The Structural Type of the Mastoid Process, Based upon the Skiagraphic Examination of 1000 Crania of Various Races of Mankind. (With epidiascope.)
Communication:
Dr. P. Watson-Williams and Mr. E. Watson-Williams: A Method of Diagnostic Exploration of the Posterior Ethmoidal Cells. (With lantern slides.)
Cases will be shown by:
Mr. Sidney Scott: A Pigeon 16 Months after a Single Application of Alcohol to the Membranous Labyrinth.
Mr. Lawson Whale: Large Exostosis Removed from Ear of Adult Male.
Mr. T. H. Just: (1) Case of Ossification of the Membrane *around a Perforation*; *(2) Tumour of External* Auditory Meatus.
Other Cases will be shown.

SECTION OF ELECTRO-THERAPEUTICS: at 8.30 P.M.
Presidential Address:
Dr. E. P. Cumberbatch: Progress in Electrology and Radiology; the Importance of Physics, Physiology, and Anatomy.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Oct. 17th.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 2 P.M., Dr. S. Pinchin: Medical Out-patients. Dr. Simson: Diseases of Women. 2.30 P.M., Dr. A. Saunders: Demonstration of Cases (Medical Wards). Mr. Addison: Visit to Surgical Wards. 5 P.M., Lecture:—Dr. A. Saunders: Digestive Troubles of Childhood.
TUESDAY.—11 A.M., Dr. McDougal: Electrical Department. 12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen. 2 P.M., Dr. Morton: X Ray Department. 2.30 P.M., Mr. T. Gray: Visit to Surgical Wards. 5 P.M., Lecture:—Dr. Pernet: Some Secondary Syphilides.
WEDNESDAY.—10 A.M., Mr. MacDonald: Genito-Urinary Department. 12 noon, Mr. Simmonds: Demonstration of Fractures. 2 P.M., Mr. D. Armour: Demonstration of Cases (Surgical Wards). Dr. Owen: Medical Out-patients. Mr. Gibb: Eye Department. 5 P.M., Lecture II.:—Mr. T. Gray: Surgery of the Mesentery.
THURSDAY.—12 noon, Dr. Pinchin: Diseases of the Heart. 2 P.M., Mr. MacDonald: Surgical Out-patients. Mr. Armour: Operations. 5 P.M., Lecture:—Dr. Snowden: The Psycho-Neuroses.
FRIDAY.—10 A.M., Mr. D. Buxton: Dental Department. 2 P.M., Dr. Burrell: Medical Out-patients. Mr. Sinclair: Surgical Out-patients. Dr. Pernet: Skin Department. 2.15 P.M., Mr. Addison: Operations. 5 P.M., Lecture:—Dr. Pritchard: Pleural Effusions.
SATURDAY.—10 A.M., Dr. Burnford: Demonstration of Cases (Medical Wards). Dr. A. Saunders: Medical Diseases of Children. 2 P.M., Mr. Simmonds: Surgical Out-patients.
Daily:—10 A.M., Visit of Post-graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, Marylebone, W.
MONDAY, Oct. 17th.—11 A.M., Dr. Goodall: Out-patients. 2 P.M., In-patients. 5.30 P.M., Lecture:—Sir S. Russell-Wells: Mitral Disease.
TUESDAY.—10 A.M., Dr. Parsons-Smith: Out-patients. 11 A.M., Dr. Price: In-patients. 2 P.M., Sir S. Russell-Wells: Out-patients.
WEDNESDAY.—10 A.M., Dr. Parkinson: Out-patients. 2 P.M., Dr. Moon: In-patients.
THURSDAY.—2 P.M., Dr. Price: Out-patients. Dr. Moon: In-patients. 6.30 P.M., Dr. Hamill: Out-patients.
FRIDAY.—10 A.M., Dr. Parsons-Smith: Out-patients. 2 P.M., Dr. Parkinson: Out-patients. 3 P.M., Dr. Parkinson: In-patients. 4 P.M., Dr. Hamill: In-patients.
SATURDAY.—10.30 A.M., Dr. Hamill: In-patients.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Oct. 20th.—4 P.M., Lecture:—Mr. T. T. Higgins: Fractures.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.
THURSDAY, Oct. 20th.—Chesterfield Lecture:—Dr. W. Griffith: The Diagnosis of Skin Diseases.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.
Post-Graduate Course on Infant and Child Welfare.
A Course of Twelve Lectures on the Management and Feeding of Infants and Young Children, by Dr. E. Pritchard to Qualified Practitioners.
WEDNESDAY, Oct. 19th.—6 P.M., Lecture V.:—The Modification of Milk.
FRIDAY.—6 P.M., Lecture VI.:—The Uses of Dried Milk and Patent Foods.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.
TUESDAY, Oct. 18th.—4.30 P.M., Dr. J. G. Clegg: Inflammations of the Cornea.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street, Whitworth Park.
THURSDAY, Oct. 20th.—4.15 P.M., Dr. N. C. Haring: Chest Troubles.

SALFORD ROYAL HOSPITAL.
THURSDAY, Oct. 20th.—4.30 P.M., Mr. Garnett Wright: Diagnosis and Treatment of Tumours of Breast.

UNIVERSITY OF SHEFFIELD.—FACULTY OF MEDICINE.
Post-Graduate Lectures and Demonstrations.
TUESDAY, Oct. 18th. (At the Royal Infirmary.)—3.30 P.M., Mr. G. H. Pooley: Common Diseases of the Eye. 4.15 P.M., Mr. E. F. Finch: Intestinal Obstruction.
FRIDAY. (At the Royal Hospital.)—3.30 P.M., Dr. A. E. Naish: Demonstration of Cardiac Cases. 4.15 P.M., Dr. P. J. Hay: Cases of Inflammation of the Cornea.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.
A Course of Eight Lectures and Discussions on Problems of Public Health in Relation to Industrial Hygiene at the Lecture Theatre of the Institute.
WEDNESDAY, Oct. 19th.—4 P.M., Lecture I.:—Sir Thomas Oliver: Problems of Industrial Hygiene in Relation to Public Health.

Appointments

KEEP, A. C., M.D., C.M. Edin., has been appointed Honorary Consulting Surgeon to the Samaritan Free Hospital for Women, Marylebone.

WARD, B. J., F.R.C.S. Eng., Honorary Surgeon, Queen's Hospital, Birmingham.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen University.—Lect. in Bio-Chemistry. £550.
Aberdeen University and North of Scotland College of Agriculture.—Physiologist. £600.
Albert Dock Hospital, Connaught-road, E.—Surg.
Barrow-in-Furness, North Lonsdale Hospital.—H.S. £225.
Bath, Royal Mineral Water Hospital.—Physician.
Bedford County Hospital.—Asst. H.S. £150.
Birmingham, Dudley-road Hospital.—Sen. Res. Asst. M.O. £450.
Bristol General Hospital.—Hon. Ophth. Surg. H.S. Cas. H.S. Each £175.
Cairo, Egyptian Government School of Medicine.—Prof. of Pathology. L.E.1200–1440.
Cambridge, Addenbrooke's Hospital.—H.S. £130.
Cancer Hospital, Fulham-road, S.W.—First Asst. to Research Dept. £750.
Capetown, Somerset Hospital.—Res. H.P. £30 per month.
Cardiff, King Edward VII. Hospital and Medical School.—Anæsth. £50.

there, and later to meet a school friend with whom he was to stay in Kent until his return to school. On the morning of departure Miss C., the friend of his parents, heard a crash outside her bedroom door, and found Oscar Gray lying at the foot of a steep staircase leading from his bedroom. He was not insensible, but appeared to her to be dazed, and later at breakfast, when he declared himself none the worse, he described his sensations by saying that he felt as if he had been "winded through the back." He was allowed to travel; and he seemed normal on the journey. At Liverpool-street Station he stooped down and drew Miss C.'s suit case from under the seat, placed it on the platform, and said good-bye to her. They had arranged to find their luggage independently. She looked round to obtain a porter, and did not notice then that he must have gone in the opposite direction from the van where his luggage was. His luggage was not claimed, and from that moment he has passed out of sight.

It may be pointed out that in a case of intentional absence a boy with not more than £2 or £3 in his pocket would not be likely to abandon his luggage, his only asset, or to leave it in the van where it might have called immediate attention to his conduct. Everything points to Gray having been a normal schoolboy, fond of his family, and giving no indication of any intention to do anything that must inevitably distress parents to whom he was especially attached. A reward for his discovery is now offered, the delay in doing this being no doubt due to the reluctance of the police to encourage those who might be tempted to extract profit for themselves from the kidnapping of helpless persons.

Gray is described as a dark-haired youth, about 5 ft. 11 in. in height, his most conspicuous mark being a scar in the neighbourhood of his hair, running downwards from near the right eyebrow.

I am, Sir, yours faithfully,

Oct. 10th, 1921. E. A. Armstrong.

REMUNERATION OF INSURANCE PRACTITIONERS.

As the sequel to correspondence between the Medical Secretary of the British Medical Association and the Ministry of Health, with regard to the proposed reduction in the capitation fee to insurance practitioners, a deputation from the Insurance Acts Committee of the Association was received by Sir Alfred Mond on Tuesday afternoon. This date was fixed in order that the result of the interview with the Minister of Health should be included in the agenda of the Panel Conference to be held in the Wesleyan Central Hall, Westminster, on Thursday next, Oct. 20th.

The deputation received from the Minister of Health the information that he considered a reduction of the capitation fee to 9*s.* 6*d.* to be necessary. The dangers of such a policy were placed before him, it being pointed out that if panel practice, owing to inadequate remuneration, should fall into disfavour with the medical profession, the serivces rendered might no longer be of the proper character and the general object of the Insurance Acts would thus be defeated. Sir Alfred Mond, however, signified no change of mind, but appealed to the patriotism of the medical profession to come to the national assistance.

A Sanatorium for Moray.—At a meeting of the Public Health Committee of the Moray County Council, held on Oct. 5th, the question was raised as to adapting the Combination Poorhouse, Bishopmill, for a sanatorium for the county (the inmates to be otherwise provided for), and a report was submitted by the clerk. The report stated that the building was in two sections, and at present there were 38 inmates, and that it might be made available for 40 patients. The institution lacks many requirements of an ideal sanatorium, and after some discussion it was agreed to take no steps for the present.

Medical News.

Examining Board in England by the Royal Colleges of Physicians of London and Surgeons of England.—At the Second Professional Examination in Anatomy and Physiology held on Sept. 29th and 30th, and Oct. 3rd, 4th, and 5th, 166 candidates presented themselves, of whom 92 were approved and 74 were rejected. The following are the names and schools of the successful candidates :—

S. Abadir, King's Coll. ; C. F. Ashby and F. Asker, St. Bart.'s ; E. A. Aslett, St. Mary's ; A. Basilios, Birmingham ; K. C. Beatty and J. Bee, London ; Susanna M. Bornman, Cape Town and London Sch. Med. ; H. B. Boucher, St. Thomas's ; S. Brest, St. Bart.'s ; S. G. Brown, London ; C. J. N. Cameron, Univ. Coll. ; R. E. D. Cargill, St. Bart.'s ; K. R. Chaudhri, Punjab and St. Mary's ; Marian B. Coleman, London Sch. Med. ; P. S. Court, Guy's ; B. Crosthwaite, Durham ; S. W. Cuff, St. Bart.'s ; S. H. Currie, London ; A. J. M. Davies, St. Mary's ; G. I. Davies, Univ. Coll. ; A. M. Deane, St. Thomas's ; G. W. R. W. Dreiheller, Middlesex ; C. L. Elgood, St. Bart.'s ; V. H. Ellis and P. F. Evans, London ; W. O. H. Evans, Bristol ; N. B. Farman, King's Coll. ; L. Freeman, St. Thomas's ; H. J. J. Garrod and A. Gelberg, Middlesex ; R. A. Grant, Guy's ; A. Harbour, King's Coll. ; C. G. Harper, Middlesex ; J. B. Hayes, King's Coll. ; F. Heckford and W. A. Hervey, St. Bart.'s ; E. W. Hicks, St. Thomas's ; A. Hooper, Leeds ; Barbara M. Hope, Cambridge ; D. V. Hubble, St. Bart.'s ; J. Hughes, Bristol ; O. R. Humphreys, Cardiff ; J. S. Jacobsz, Guy's ; D. T. Jenkins, Edinburgh ; Millicent Jervis, King's Coll. ; R. A. V. Jones, London ; J. Joseph, Middlesex ; A. Jowell, Guy's ; Abraham Jowell, Cape Town and Guy's ; Marjorie A. M. Lambert, London Sch. Med. ; J. J. Laws and H. E. Lewis, Guy's ; W. R. A. Line, Birmingham ; M. F. B. Lynch, London ; G. A. McKaig, St. Thomas's ; R. S. MacLatchy, London ; E. L. Martin, King's Coll. ; L. M. Maybury, Cambridge ; E. B. Messinier, Middlesex ; G. O. Morgan, Cardiff ; C. T. Norris, London ; K. E. Nosseir, Sheffield ; R. J. Oliver, London ; Dorothy Parsons, London Sch. Med. ; G. M. Pennant, Cardiff ; S. C. Prior, Birmingham ; C. B. Rich, King's Coll. ; E. J. H. Roth, St. Bart.'s ; B. Rubinstein and M. Rubinstein, Guy's ; E. J. Ryan-MacMahon, St. Thomas's ; J. Shutt, Leeds ; V. Sinnetamby, Ceylon and Middlesex ; C. R. Steel, St. Bart.'s ; E. G. Steeler, King's Coll. ; K. H. Tan, Middlesex ; Ada Taylor, Univ. Coll. ; M. Taylor, Guy's ; E. J. Thomas, Cardiff ; R. D. M. Tims, Cambridge and St. Thomas's ; R. W. H. Tincker, St. Bart.'s ; P. W. Tobin, St. Mary's ; V. C. Tughan, Univ. Coll. ; D. C. Vaughan, Manchester ; Kathleen M. Ward, Liverpool ; H. C. Warner, Guy's ; T. M. Wilks, King's Coll. ; J. H. Williams, London ; T. J. Wilson, St. Bart.'s ; J. Wolstencroft, Liverpool ; and G. C. Young, King's Coll.

Materia Medica and Pharmacology.—S. Abadir, King's Coll. ; G. N. Beeston, Charing Cross ; J. L. Brown, King's Coll. ; H. B. Boucher and A. J. S. L. Boyd, St. Thomas's ; G. H. Buncombe, St. Bart.'s ; A. R. Cox, Guy's ; A. Davies, Cardiff ; G. W. R. W. Dreiheller, Middlesex ; F. W. Dunn, Charing Cross ; R. A. Dyke, Guy's ; W. Egan, King's Coll. ; G. I. Evans, Manchester ; T. P. Evans, Charing Cross ; R. G. Flower, Leeds ; C. S. Forrest, Manchester ; A. R. Fox, Middlesex ; T. F. Fox, Guy's ; J. F. Hamber and A. Harbour, King's Coll. ; Katie E. Hudson, London Sch. Med. ; N. H. Ibrahim, Sheffield ; C. W. Jones, Cardiff ; R. D. Jones, Edinburgh and Middlesex ; G. B. Kirkland, Guy's ; Marjorie A. M. Lambert, London Sch. Med. ; M. M. Lewin and G. A. McKaig, St. Thomas's ; C. F. Morrison, Guy's ; W. R. Nash, Cardiff ; R. A. Newsom, King's Coll. ; R. E. Overton, Univ. Coll. ; Dorothy Parsons, London Sch. Med. ; G. M. Pennant, Cardiff ; P. J. J. Pienaar, St. Thomas's ; A. Pierce, Birmingham ; M. Rubinstein, Guy's ; A. Sherning, St. Thomas's ; J. Shutt, Leeds ; R. F. Smith, Guy's ; B. L. Steele, Univ. Coll. ; E. G. Steeler, King's Coll. ; M. Taylor, Guy's ; O. F. Thomas, Manchester ; V. C. Tughan, Univ. Coll. ; W. R. van Langenberg, Middlesex ; D. C. Vaughan, Manchester ; R. L. Washington, Birmingham ; M. Weisman, Manchester ; F. E. C. Williams, St. Bart.'s ; H. H. Williams, Liverpool and Middlesex ; and T. Yoxall, Birmingham.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.—The following candidates having passed the requisite examinations have been admitted Diplomates in Public Health :—

Alfred F. Adamson, Isabella M. M. Aitken, William R. Clayton-Heslop, Edward M. E. Cumming, William Cunningham, Andrew Davidson, Andrew M. Davidson, Jean D. Don, David Fyfe, Janet Grant, Donald C. Lamont, Isabel Macfie, William McKendrick, Jane S. McPhail, George Morris, Taylor D. Murison, Evan W. Richards, Helena J. Robertson, Richard Sandilands, John W. Simpson, Alexander D. Stewart, and Mary C. Walker.

Royal Faculty of Physicians and Surgeons of Glasgow.—At a meeting held on Oct. 3rd the following were admitted (after examination) as Fellows of Faculty :—

George Bell Brand, M.B., Ch. B. ; John Williamson Dalgleish, M.B., Ch.B.; John Rennie Carrie Gordon, L.R.C.P., L.R.C.S., L.R.F.P.S.G. ; Madari Audia Keshvalu, M.R.C.S.Eng. L.R.C.P.Lond. ; John Wilson Leitch, M.B., Ch.B.

for infants and for children in the first five years of life, historically has been and administratively now forms the chief means for reducing the mischief done by this great enemy of mankind.

A similar difficulty arises in measuring the value of the work of health centres and of public health nurses in reducing infant mortality. Did we possess quantitative knowledge of the value of each factor influencing infantile health and disease, *and were we able to measure the extent of action of each* factor, it would be possible to assess the relative importance of each factor concerned in producing or preventing infantile sickness and mortality. But we usually cannot do this. It is not difficult to show curves of infant mortality for different cities, almost exactly parallel in a long series of years, in some of which health centres and public health nurses have been actively at work, while in others their number has been few or there have been none. Furthermore, such curves are not unnaturally flourished before us by economists, as well as by biometricians, as prima facie evidence of the inutility of the educational and medical work of physicians and nurses in child welfare work. But these confident assertions leave us quite cold ! Were all the gross mass figures which could be marshalled to point to the conclusion that ignorance is no worse than knowledge, and that domestic cleanliness is not worth while, we should very properly doubt their accuracy or their teaching, not the merits of sanitary education and practice. In actual fact we can by comparison of carefully selected areas in different towns show the value of sanitation and instruction in reducing infant mortality, although —*inasmuch as with these two factors other factors are also* concerned for which accurate information cannot be tabulated—we are in most instances "up against" the impossibility of measuring the value of each single factor satisfactorily. In short, in a large part of public health work we must content ourselves with the fact that our work is on the lines which our knowledge of physiology, pathology, and medicine—the institutes of medicine—shows to be important, and reserve to the future the possibility of securing non-fallacious measurements of complex social influences.

Vital Statistics a Means to an End.

Although the examples just cited display my unwillingness to submit to the sole arbitrament of arithmetical standards in the measurement of results of public health work—when pathology and medicine give accurate guidance—I would not convey the impression that *vital statistics fail to give most* valuable guidance and leading in public health work; they are, indeed, indispensable for such work.

I have always regarded vital statistics as a means to an end, and not an end in itself, and my own first acquaintance with the subject arose out of the need to study these statistics, to which in the third quarter of the last century there was no English guide extant. The publication of my "Elements of Vital Statistics" led to personal contact and correspondence with medical statisticians in many countries; a relationship which became more extensive and more valuable as epidemiological investigations on successive subjects formed my fascinating task. I recall, for instance, investigations which I undertook into pandemics of rheumatic fever and of diphtheria, for the first of which scarcely any records from America were available; but in diphtheria there was *ample evidence from this country showing the* natural tendency of diphtheria to be more extensively continental than insular in its incidence, and for its endemic prevalence to be on such a scale as to disguise partially the epidemic characteristics of the disease. At a later period I recall an international inquiry in which Dr. T. H. C. Stevenson, now the distinguished medical statistician of the English Government, and I were engaged, in which it was desired to obtain corrected birth-rates for different cities, making arithmetical allowance for the proportion of married women in the population and for their age. And it will not be surprising to some of you to learn that the most valuable records available in America were those compiled by Dr. C. V. Chapin for the city of Providence (Rhode Island), records which, with similar records from Boston, showed that the American born in these cities had reached a position as regards fertility almost as low as that of Paris.

Birth and Death Registration.

During the last 10 years the value and scope of American vital statistics have greatly increased; and in addition to the important publications of the Federal and State governments, *your literature has been enriched*, and the borders of knowledge extended, by the publications of many workers, including Dr. Hoffman, of the Prudential Insurance Company, and Dr. Louis Dublin, of the Metropolitan Life Insurance Company. To both of these gentlemen I have been indebted for valuable references and information during the last two winters while lecturing in the Johns Hopkins University.

Your death registration area and your birth registration area have become extended, and the accuracy and completeness of registration have increased, though it is evident that much more needs to be done; and it remains an anomalous fact that in a community which prides itself, and rightly, on its business capacity, and which makes almost a religion of efficiency methods, there is a serious lack of driving power to secure from every community throughout the States the accurate data of births, sickness, and deaths without which periodic vital stock-taking is impracticable. In England Benjamin Ward Richardson could say many years ago, referring to Farr's epoch-making reports, that it is "no longer true that pestilence walketh in the dark. It is measured and registered, walketh at last in the open day." This is becoming more nearly true for the United States, though in many areas there is still inaccurate certification of deaths and unskilled classification of the returns in statistical offices; and the records of sickness are imperfect. A few years ago in many States the registration of births was so incomplete that it was impossible to determine whether any apparent decrease in the rate of infant mortality was real, or was due in part or entirely to "drives" which had been followed by improved registration of births. This, happily, is being improved, but the margin of error in many areas is still a serious handicap in statistical inquiries.

Special Difficulties in America.

Among the difficulties in the way *of an accurate national* system of registration of births and deaths may be named the following:—

1. America is the subject of the vastest experiment in the world's history in mixture of races. Not only has it a large negro population and a not inconsiderable population of the red and yellow races; but Anglo-Saxons, Germans, French, Slavs, Italians, Jews and other peoples are adding to its population year by year; and although the Anglo-Saxon element still predominates, this preponderance will cease ere long unless relative race birth-rates greatly change; and the largest element on this continent will be no longer Anglo-Saxon. Happily, the American population of the future will still possess the glorious heritage of law and language, of freedom and self-government, and of moral ideals, with which the name of Anglo-Saxon is rightly associated. With *such a conglomerate and mobile population*, with problems of digestion and assimilation of foreign elements on an enormous scale, it is not surprising that registration of births and deaths, with its possibilities of measuring the relative vitality and social progress of different social elements, has been neglected. It *is none the less a misfortune for humanity* that accurate and complete records have not been kept of the greatest social and sanitary experiment in the world's history.

2. The State sovereignty of each of the 48 States has been inimical to the compilation of accurate comparable national statistics. The Bureau of Vital Statistics in the Department of Commerce of the Federal Government publishes annual reports which year by year are increasing in value; but water cannot spontaneously rise above its own level, and these reports have no higher value than that of the records of each individual State. Although the international rules as to classification of deaths are well known, what certainty have we that in the majority of these States these rules are rightly followed in the allocation of deaths to their appropriate heading? It would probably be *impracticable for the Federal Government*, in view of the magnitude of the task and the separate sovereignty of each State to arrange for a Federal as well as a State analysis of every single death in the country, thus ensuring exactly comparable data. This has been done in England, thus giving an accurate check on the locally published vital statistics for every sanitary area throughout the country, and rendering these statistics of local mortality comparable with those for all other areas.

3. In the majority of States the lack of civil service conditions of appointment and tenure of office of the statistical superintendent, has, I gather, meant much inefficient work. This is pre-eminently an appointment in which evidence of competence for the post should be demanded. The majority of State statisticians in the past have been untrained physicians, with no special interest in the compilation of accurate statistics; many were not concerned with enforcing the law of registration, and were ignorant of the principles of death certification and classification. In the General Register Office in London there is a medical statistician, a worthy successor of Dr. Farr, who has associated with him a staff competent to undertake *all the needed* tabular work, and who can call in the services of actuarial consultants when required. This secures a due performance of the work of registration, tabulation of results, and commentary on the classified results. The knowledge of a fully trained scientific physician, an adequate training in the principles of death certification, and of the classification of diseases, are indispensable in collecting and in utilising vital statistics; and many well-intentioned investigations by biometricians, so-called, have shown what ridiculous results may be published in the absence of accurate pathological and medical knowledge. Complexes are treated as

towards their maintenance according to their means. In conclusion the president welcomed Sir John Bland-Sutton, whom he described as the John Hunter of the present day. The Earl of Athlone, in reply, signified his gratification that the hospital had been enabled to carry on its work under the voluntary system. The Dean, Mr. A. E. Webb-Johnson, emphasised the need for the endowment of further professorial chairs in the medical school. Sir John Bland-Sutton, in rising to reply to the toast of the Guests, was received with an ovation which indicated the affection and esteem in which he is held by all generations of Middlesex men. The evening closed with the proposal of the health of the President by Dr. Campbell Thomson, and this toast was very warmly received.

St. Thomas's Hospital Old Students' Dinner.—This dinner will be held on Friday, Oct. 28th, at 7 for 7.30 P.M., at the Wharncliffe Rooms, Hotel Great Central, London, N.W., Dr. H. W. G. Mackenzie in the chair.

Prince of Wales's General Hospital Reunion. The inaugural dinner will be held at the Trocadéro Restaurant, Piccadilly-circus, on Thursday, Oct. 27th, at 7.30 for 8 P.M. Past residents and students of the hospital who have not received a notice can obtain further particulars from Mr. H. W. Carson, 111, Harley-street, London, W. 1.

Post-graduate Lectures on Pediatrics.—Under the auspices of the Fellowship of Medicine and Post-Graduate Medical Association a course of 12 practical lectures on Gastro-intestinal Affections in Children will be given at "The Children's Clinic," Western General Dispensary, Marylebone-road, London, N.W. 1, on Mondays and Thursdays at 4.45 P.M. The first lecture will be given on Oct. 17th by Prof. W. Bayliss on the Physiology of Digestion. Subsequent lectures will be given by Dr. Bernard Myers, Dr. T. Joekes, Dr. H. E. Archer, Dr. G. Low, Dr. J. G. Thomson, Mr. Tyrrell Gray, and Dr. Martin Berry. The fee for the course to Fellowship members is 1½ guineas, and 2 guineas to non-members. A detailed syllabus and tickets can be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole-street, W. 1.

West Kent Medico-Chirurgical Society.—The first meeting of the session will be held at the Miller General Hospital, Greenwich, to-day (Friday), at 8.45 P.M. The President, Dr. A. M. Cato, will preside, and cases will be shown by Dr. E. P. Cumberbatch, Dr. Montague Hine, Mr. Willmott Evans, and Mr. O. A. Joll. The next meeting will be held on Nov. 11th, when Mr. P. B. Roth will read a paper on Treatment of Fractures. On Dec. 9th the Purvis Oration will be delivered by Sir James Purves Stewart on Respiratory Disorders of Nervous Origin. Jan. 13th will be devoted to a Clinical Evening. On Feb. 10th Dr. C. O. Hawthorne will read a paper on Some Pulse Tracings and their Meanings. On March 10th Mr. C. J. S. Thompson, Curator of the Wellcome Historical Museums, will speak on Parturition Chairs, their History and Use; and on April 14th Mr. Ernest B. Dowsett will discuss Pyorrhœa Alveolaris. On May 12th the presidential address will be delivered. The annual subscription to the Society is 10*s.* 6*d.*, and the Hon. Secretary is Dr. C. J. B. Buchan, 326, Brownhill-road, Catford, London, S.E.

Royal Free Hospital Medical Society.—A meeting was held on Oct. 6th, Dr. G. Scott Williamson in the chair. The meeting took the form of a debate in which Lady Barrett proposed the motion that Vaccination is a Prophylactic against Small-pox. She said that it had been established as a result of observation that those who had had cow-pox were not liable to small-pox; inoculation experiments had been done to prove this. The effect of extensive child vaccination in this country had been to change the age-incidence of small-pox from childhood to the adult life when effects of vaccination had passed off. Small-pox undoubtedly occurred in a modified form in those who had previously been vaccinated, whereas revaccination of adults had been successful in preventing small-pox. Lady Barrett quoted statistics in support of her statements. Dr. W. R. Hadwen, in opposing, said that it was a dairymaid's superstition that vaccination protected against small-pox. The change of age-incidence was not conclusive, since in the seventeenth century small-pox had been a disease of adults; also, influenza showed a similar periodic age-incidence. The mortality of small-pox had not been altered since the introduction of vaccination. He thought that the diminishing incidence and modified type of small-pox were purely due to improved sanitation with its beneficial effects on child life. The death-rate from small-pox in the unvaccinated children had fallen in the same proportion as in the vaccinated, and the effects of revaccination did not show any protective action. The President contended that science had neither proved nor disproved the value of vaccination as a prophylactic.

Society of Medical Officers of Health: Annual Dinner.—The annual dinner will be held at the Café Royal, Regent-street, London, W., on Friday, Oct. 21st. A few tickets are still obtainable (price 15*s.*) from the Executive Secretary, 1, Upper Montague-street, Russell-square, London, W.C. 1.

London Dermatological Society.—A meeting will be held at 4.30 P.M. on Tuesday, Oct. 18th, at St. John's Hospital, 49, Leicester-square, London, W.C., when clinical cases will be shown. At 5 P.M. the opening address will be delivered by Sir W. Arbuthnot Lane on the Changes of the Skin in Chronic Intestinal Stasis.

Royal College of Surgeons in Ireland.—At the last meeting of the Council of the College, Mr. G. J. Johnston was re-elected Professor of Surgery in the school of the College; Dr. R. J. Rowlette was elected Professor of Pharmacology; and Dr. J. W. Bigger was elected Professor of Preventive Medicine and Medical Jurisprudence. The two latter appointments were made on the nomination of the President and Fellows of the Royal College of Physicians of Ireland.

Société de Psychothérapie: Annual Meeting. The twenty-fourth annual meeting of this society will be held on Tuesday, Oct. 18th, at 4 P.M., and on Wednesday, the 19th, at 10 A.M., at 49, rue Saint-André-des-Arts, Paris. The annual banquet will take place on the 18th. The programme of the meeting will include an account of Mr. J. Voisin's works on psychotherapy, and discussions on psychotherapy, its progress and its actual orientation, and on the influence of race in nervous and mental diseases. Individual communications will be welcomed. Foreign physicians specialising in psychotherapy are invited to take part in the discussions and to make communications at this séance of the society, of which Mr. J. Voisin is president. Those desiring to be present are invited to write to the secretary, Monsieur Bérillon, 4, rue de Castellane, Paris, VIIIe.

Leicester Royal Infirmary.—A great effort is being made to raise the sum of £100,000 in recognition of the 150th anniversary of this infirmary. It is proposed to try to obtain the money by the "Unit" system, the sum of 12*s.* 6*d.* represents a "unit," being made up of 150 pennies—a penny for every year that the Infirmary has been opened. The city is being asked to raise 112,000 units and the county 48,000 units, these totals being based on the numbers of patients received in 1920 from the city and county. A table has been arranged showing the amount of units required from citizens of Leicester rated at various sums, and the country parishes will be asked to subscribe at the rate of approximately one unit for every four residents. A number of business houses and private residents have already indicated their willingness to adopt the system. Contributions should be sent to the house governor and secretary at the Leicester Royal Infirmary.

Royal Microscopical Society.—The annual conversazione of this society was held at the Mortimer Halls on Wednesday, Oct. 5th. The President, Prof. John Eyre, M.D., received the guests in the Upper Hall, in which the members of the society had arranged a large and interesting collection of pond-life exhibits. Among the most appreciated were beautiful preparations of diatoms, sun animalcule, water-fleas stained while alive with neutral red, and plumatella shown against brilliant coloured backgrounds obtained by means of Rheinberg's discs. In the Lower Hall most of the important microscope firms had stands exhibiting modern instruments of all kinds. During the evening Dr. J. A. Murray gave lantern demonstrations on the cellular structure of the body in an adjoining room, which was all too small to accommodate those who wished to see the slides.

Birmingham Women's Hospital.—This hospital celebrated its jubilee on Oct. 3rd. In 1871 the hospital began its existence in a building in the Crescent; seven years later an out-patient department was opened in the Upper Priory and in the same year the in-patient department was transferred to Sparkhill. In 1901 an entirely new and admirably designed hospital was built. In 1911 the hospital took over the management of the Maternity Hospital, which was founded in 1842. To-day there are 175 beds under the care of the committee. During the 50 years 35,000 in-patients have been treated. Last year there were 2760 in-patients, 20,000 attendances as out-patients, 600 cases in convalescent homes, and 85 pupils were trained for the C.M.B. certificate; 1500 district maternity cases were visited. The hospital was the first women's hospital to have a medical woman on the staff and to have an equal number of men and women on the committee. To-day there are nine medical women associated with the two hospitals.

assistance are provided for the expectant parturient and nursing mother. The statistical differences in neo-natal mortality, and it may be added in the number of still-births, in different areas amply confirm this conclusion.

The definition of still-births adopted in different states varies, and apart from this there are large differences in the extent to which such births are registered, and to propose, as has been done, to state puerperal mortality in terms of total including still-births, instead of in terms of live-births is to depart from the nearest approach to an accurate denominator for the rate hitherto available.

Natural Limitations of Biometrics.

In conclusion let me, while expressing my appreciation of the essential rôle of vital statistics as an instrument in extending our knowledge of the epidemiology and social history of each disease (its social history is really a part of its epidemiology) in estimating the relative position of different communities, and in assessing the value of sanitary and social work, deprecate the statistical use of groups of diseases, of *multiform and heterogeneous origin, for comparative purposes* as being just as unscientific as it would be for the biometrician or the chemist to insist or even to permit himself to study the properties of hydrogen in the contents of a jar containing a mixture of this gas with half a dozen other gaseous elements. I further press the point that vital statistics can have no higher value than that of the individual death certificates on which they are based; that no conjuring with classifications will render indefinite and dubious data other than they are; and that the only line of safety in most instances is to study each certified cause of death independently and separately.

I would, finally, emphasise the important consideration that when facts having only a qualitative and compound value are being studied, and when the factors concerned cannot—as is so often the case—be analysed quantitatively, we are justified in denying, indeed it is our duty to deny, the value of "biometrical" work based on such data, and *in resting our inferences and our administrative action,* as guardians of the public health, on a careful balance of all available evidence, giving chief place to exact physiological and pathological evidence bearing on our problem.

VACCINATION IN THE NORTH-WEST FRONTIER PROVINCE.

IN his report on vaccination in the North-West Frontier Province of India for the year 1920–21, Lieut.-Colonel W. M. Anderson, I.M.S., states that the total number of vaccinations performed during the year was 116,167 against 131,532 in the preceding year. 2073 deaths from small-pox were recorded. The attitude of the people towards vaccination is, on the whole, favourable. Revaccination, however, is considered unnecessary and troublesome, except when small-pox prevails in epidemic form. There is no religious prejudice against vaccination. Diminution in the number vaccinated is attributed to discontent among the vaccination staff caused by their inadequate pay.

ABERDEEN UNIVERSITY ROLL OF SERVICE.

THE Aberdeen University "Roll of Service in the Great War" (Aberdeen University Press. 21*s.*), edited by Miss Mabel Allardyce, with a Foreword by Principal Sir George Adam Smith, has recently been published. The Roll of Service includes biographies, and in nearly all instances portraits also, of the 341 members of the University who gave their lives, and gives the service records of the 2852 graduates, alumni, and students who served with the forces or did work of national importance. There are also two Appendices, one dealing with the service of University officials and the other giving a list of civilian prisoners of war.

MEDICINE AND WHITAKER'S ALMANACK.

THE board of directors of J. Whitaker and Sons, Ltd., proprietors and publishers of "Whitaker's Almanack," has been strengthened by the inclusion of Mr. Edgar Whitaker, who has relinquished his ophthalmological practice at Palmerston North, New Zealand, and returned to England for the purpose. The reconstructed board consists of three sons of the late Mr. J. Whitaker, F.S.A., who founded the annual bearing his name in 1868, and edited it until his death in 1895. Mr. G. H. Whitaker, M.R.C.S., F.R.S.A. (managing director), is this year Master of the Woolmen's Company. Mr. C. W. Whitaker, M.A., F.S.A. (editor), who is a member of the Common Council of London and chairman of the Central Markets Committee. Mr. E. Whitaker, M.R.C.S., L.R.C.P. (business manager), who served in the South African War and was gazetted to the Royal N.Z. Artillery at the outbreak of the Great War, was at the time of leaving New Zealand chief ophthalmic surgeon and treasurer of the Palmerston North Hospital Board, one of the largest and best-equipped hospital boards in the Dominion, which has recently been enlarged and equipped with the latest X ray and bacteriological departments to the total cost of £50,000. He was recently President of the Palmerston North B.M.A. (1919–20).

MOTHER'S AID CENTRES IN VIENNA.

ACCORDING to the Record of the Save the Children Fund of Oct. 1st there are now 56 Mothers' Aid Centres in Vienna. Infants and children up to 6 are examined under the double inspection of a doctor and a child-welfare visitor, who follows up the case, sees that the doctor's advice is carried out, and so constitutes an invaluable safeguard in the case of delicate children. It is announced by the Vienna Jugendamt that one of these visitors is now to be attached to every school. This effort of Vienna to help herself has been supported by the Friends' Relief Committee, and the American Relief Administration also takes a warm interest therein.

A bad omen for the winter now ahead is the renewed depreciation of the crown in Vienna (30 Austrian crowns are now equal to about 3*d.*), and the sudden leap in the prices of the necessities of life, such as flour, bread, and especially fat, which has almost disappeared from the market. Since the beginning of August flour has risen from 14 to 30 kronen, bread from 9 to 15 kronen, fat from 180 to 420 kronen. New and terrible privations, such as those experienced in 1918, are expected by old inhabitants of Vienna, who have experienced all the phases of the Austrian catastrophe.

HYGIENE AND MEDICINE IN SCOTLAND, 1745–1900.

AT the annual meeting of the Caledonian Medical Society, held recently at the Royal College of Physicians, Edinburgh, the presidential address delivered by Prof. William Russell took the form of a survey of the social and medical development of Scotland from 1745 to the beginning of the twentieth century. After a brief reference to the prehistoric and historic blending of races, and to the establishment after Bannockburn of a corporate and independent Scots kingdom, Prof. Russell proceeded to show how housing, sanitary, and labour conditions, natural enough in *rural communities, became monstrous* when massed in towns, where the iniquity of female and child labour eventually roused thinking people, so that it became possible to legislate for the protection of women and children. The outcome took the forms of sanitary legislation, housing schemes, maternity and child welfare schemes. With reference to the development of medicine during the period under review, Prof. Russell began with the name of William Cullen's "First Lines of the Practice of Physic, including the Definitions of the Nosology," in which were reviewed the systems of medical thought current in that period—the period of the search for an underlying principle that might explain health and disease—and also referred to William Pulteney Allison's "Outlines of Physiology and Pathology," showing how the schools of medical theorists were gradually displaced by the revelations and discoveries attained by accurate observation and laborious investigation. The beginnings of emancipation from the tyranny of metaphysics were greatly strengthened by the appearance of Laennec's "Mediate Auscultation" in 1819, and its translation by Forbes in 1838. Controversies over principles were replaced by observation; with Laennec modern medicine really began. Two other landmarks were Pavlov's "The Work of the Digestive Glands" and Metchnikoff's "Comparative Pathology of Inflammation." As an example of the necessity of physiological knowledge before a generalisation is possible, Prof. Russell pointed out how arteriosclerosis was still regarded as a natural and normal change characteristic of advancing years, whereas when full acceptance was reached of the physiological laws which acted upon the blood vascular system, the span of life would be lengthened to all who were not cut down by some acute or infective malady.

THE LANCET: SUBSCRIPTION RATES.

THE Chief Inspector of Factories announces the following vacant appointments: Finedon (Northampton), Purfleet (Essex).

Births, Marriages, and Deaths.

BIRTHS.

CUTLER.—On Oct. 1st, at Kensington House, Dudley-road, Hastings, the wife of F. J. Cutler, M.R.C.S., L.R.C.P., of a daughter.

PARKINSON.—On Oct. 2nd, at 1, Devonshire-place, W. 1, the wife of John Parkinson, M.D., M.R.C.P., of a daughter.

THATCHER.—On Oct. 4th, at Walker-street, Edinburgh, the wife of Surgeon Lieut.-Commander Malcolm Thatcher, R.N., of a daughter.

MARRIAGES.

CLAPHAM—PAYNE.—On Oct. 4th, at St. Mark's Church, Peterborough, Harold Clapham, M.R.C.S., L.R.C.P., Park-road, Peterborough, to Gladys Mary, younger daughter of the late George Speke Payne, M.R.C.S., L.S.A., of Peterborough.

DEATHS.

MILLER.—On Oct. 2nd, James Duff Miller, M.B., C.M. Edin., L.S.A.

PENFOLD.—On Sept. 30th, at Mardale House, Rainham, Kent, Frederick William Henry Penfold, M.R.C.S. (Eng.), L.R.C.P. (Edin.), in his 62nd year.

RAINE.—On Oct. 3rd, at Orwell House, Darlington, George Rolph Raine, M.D.

STONE.—On Saturday, Oct. 1st, at 3E, Maida Vale Mansions, W. 9, William Domett Stone, M.D., F.R.C.S., &c., younger son of the late Thomas Madden and Honor Stone, aged 81 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

GREAT NORTHERN CENTRAL HOSPITAL.—Lord Islington will preside at a meeting at the Mansion House in aid of the Great Northern Hospital, on St. Luke's Eve, Monday next, at 3 P.M.

AN address will be delivered to the members of the London Chamber of Commerce on the Petroleum Problem as Affecting British Industry, by Mr. A. Beeby Thompson, M.I.Mech.E., in the Council Room of the Chamber, on Monday next, Oct. 17th, at 2.30 P.M.

DONATIONS AND BEQUESTS.—By the will of the late Mr. John Charles Pipe, of Ipswich, the testator gives £1000 each to the East Suffolk and Ipswich Hospital; St. Bartholomew's Hospital, London; Dr. Barnardo's Homes; and the Home for Incurables, Streatham; and £250 to the Samaritan Society, Ipswich. The residue of the estate, after certain beneficiaries are provided for, will also accrue to these and other institutions.

Notes, Short Comments, and Answers to Correspondents.

VITAL STATISTICS:

THEIR BETTER USE IN PUBLIC HEALTH ADMINISTRATION.[1]

BY SIR ARTHUR NEWSHOLME, K.C.B., M.D. LOND

VITAL statistics or biometrics occupy in public health teaching and administration an essentially subsidiary position, being one of several tools which the public health worker employs in his pursuit of knowledge and measurement of results. To place them on an equal footing with the fundamental sciences of biology, chemistry and physics, and of pathology, preventive medicine, and epidemiology in public health administration, or in an organised programme *for the training of public health officers*, appears to me to imply confusion of thought and of plans.

In their present stage of development in most communities, vital statistics form an excellent servant but a very bad master for the health officer. They have been invaluable in *stimulating and in guiding past public health* effort, and especially in directing attention to the areas of excessive general mortality, and of excessive mortality in infancy and from special definite causes of mortality; but medical certification, especially with regard to the more general and so-called constitutional diseases, is still defective, and conclusions based on municipal or national statistics dealing with this certification must be held in suspicion. Even under more definite headings we need to bear in mind the necessary limitations of statistical inference. Mass statistics give information which is inferior in value to the information derived from the intensive investigation of individual cases—the dynamic method of study. As James Clerk Maxwell said, "however imperfect the dynamic study of man may be in practice, it evidently is the *only perfect method in* principle," its shortcomings arising not from a faulty method of procedure, but from the limitations of our powers. On the other hand, results obtained by the statistical method "belong to a different department from the domain of exact science."

Inductions which Cannot be Stated Quantitatively.

Many inductions in causation and in the preventive or clinical treatment of disease cannot, with our present knowledge, be expressed otherwise than qualitatively, and yet they are as well established as if they could be stated *quantitatively. This is especially true for inductions as to* the results of some forms of sanitary and social effort. Two instances may be adduced.

It is often difficult to show any quantitative relation between the amount of sanitary and social effort and the reduction in the death-rate from tuberculosis. This relation evidently must be one between the total prevalence of the disease and opportunities for its communication on the one hand, and the totality of measures taken or operating for its prevention on the other hand. Were it possible to measure and weigh exactly the value and the extent of action of each factor concerned, the relation could be shown; but we do *not possess adequate knowledge for this purpose.* We know, for instance, that the conditions of urban life conduce to increased tuberculosis. We know also that the death-rate from tuberculosis has declined to a greater extent in cities than in country districts. Were we able to state quantitatively the *influence and the extent of action of, say*, overcrowding, indoor and dusty occupations, dirty habits, &c., in increasing tuberculosis, and of improvements in domestic cleanliness in habits and homes, in greater segregation of the sick, in better factory hygiene, and in higher nutrition in diminishing tuberculosis, we could measure the relative share of each of these factors in the given result in any community. Failing this, as public administrators we possess the wider outlook of physicians and of students of social phenomena, and we are satisfied that the precise teaching of pathology, the exact scientific experience in Denmark and in this country in the elimination of tuberculosis from herds of cattle, the analogous experience with leprosy, and the facts which we possess confirming our pathological knowledge and showing historical relation between hospitalisation of tuberculous patients in different communities and reduction in the tuberculosis death-rate, *all point to the conclusion that to diminish infection from* open cases of tuberculosis, and especially to diminish this which operation he introduced into Italy. He relates that in his travels in France he had seen two women in Toulouse who had been delivered by Cæsarean section, one of whom had since been happily delivered nine times. To commend the operation to his countrymen he wrote that it was as well known in France as bleeding for headache in Italy.[3] This passage was erroneously rendered by Welsch, who published a German translation of "La Comare" in 1653, "so gewöhnlich in Frankreich als das Aderlassen in Italien"—"as *common* (or *usual*) in France as bloodletting in Italy"—whereas Scipione Mercurio only said it was *as well known*. This error has often been repeated by subsequent writers, and has been used to throw doubt on Mercurio's accuracy. In this work Mercurio is the first author to mention contraction of the pelvis as an indication for Cæsarean section. It contains a description and illustration of the "hanging-legs" position for delivery in cases of contracted pelvis, which Walcher published in 1889 as something new, and also a description of the operation of bimanual version, generally associated with the name of a distinguished Fellow of this College, the late Dr. Braxton Hicks. (Figs. 2 and 3.)

---

[1] The substance of an address delivered before the American Statistical Association in New York City on April 15th, 1921.

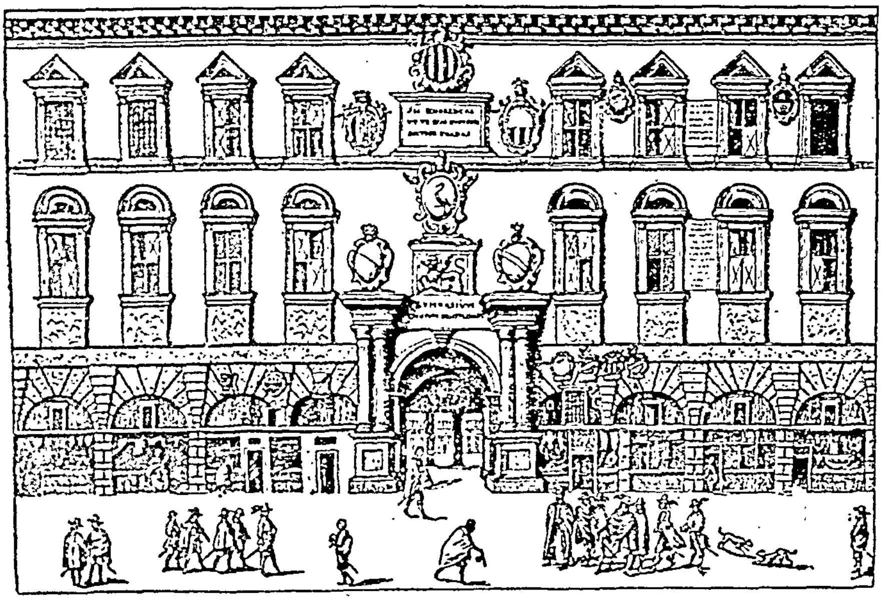

FIG. 1.—The façade of the University building at Padua at the beginning of the seventeenth century (from Guzzoni's "L'Italia Ostetrica," 1911).

It is interesting to find that the first Italian book on midwifery was a cinque cento production and was published by a Paduan obstetrician four years before Harvey went to that University. It can hardly have failed to arouse Harvey's interest, must have had an effect in popularising Cæsarean section on the living, and may have been the stimulus to Harvey to emulate the Paduan obstetrician by writing his "De partu," the first original English work on midwifery.

POSITION OF OBSTETRICS AT THE END OF THE SIXTEENTH CENTURY.

It was under the influence of such men as the above named that Harvey was led to write his great work on generation and labour. In order to appraise this work it is necessary to consider the position of obstetrics at the end of the sixteenth and the beginning of the seventeenth century. Italy was the first country in Europe to encourage anatomical research. At the School of Salerno in 1238 it was ordered that every five years a human corpse should be dissected before the students of medicine and surgery, and in 1442 two corpses were annually provided free of cost for dissection in the University. In Mundinus's work on Anatomy,[4] written in 1316, is the first description of the dissection of the human body since ancient times. The progress of anatomical study in Italy was favoured by the ancient Lex Regia, which enacted that no pregnant woman should be buried until the fœtus had been cut out of the womb, and by the ritual of the Roman Catholic Church which prescribed "if a pregnant woman die the fœtus shall be cautiously extracted as soon as possible and, if alive, shall be baptised"; which led to a great extension of the operation of Cæsarean section on the dead, especially during the frequent epidemics of plague,[5] and we have seen that the operation on the living woman had been introduced by Scipione Mercurio four years before Harvey began his studies.

France, in the person of Ambroise Paré, had begun to progress in midwifery even before Italy. But in England the art of obstetrics was neglected. There was no original work on midwifery in the English language, only translations of Rhodion, Guillemeau, and Paré were available. The ordinary practice of midwifery was in the hands of midwives who, although practising as specialists since the dawn of history, had failed to develop the science or advance the art or dignity of their calling. They were mostly recruited from an uneducated class and their characters were not beyond reproach. Some of them resembled Terence's midwife, Lesbia:—

> "Sane pol illa temulenta est mulier et temeraria
> Nec satis digna cui committas primo partu mulierem."

They were bitterly opposed to the doctors, who were only called in to difficult and operative cases, which were often rendered fatal by the ignorance and brutality of the midwives. The doctors, on the other hand, having little experience of normal cases, were apt to intervene too soon, especially when instruments, hooks and (later) forceps were employed. Only in France, where the modern development of midwifery began, had midwives attained any considerable position.

In 1598, the first of the great French midwives, Louise Bourgeois, obtained her diploma. Her examiners consisted of a physician, two surgeons, and two midwives. As the candidate was the wife of an army surgeon, one of the two examining midwives was of the opinion that Louise Bourgeois ought not to be admitted, her reason being that "she and the doctors would have a secret understanding like pickpockets at a fair." We see here the beginnings of the rivalry between midwives and doctors which was to lead up to that remarkable series of lampoons on the man-midwife in the eighteenth century and subsequently, echoes of which have been heard from time to time, even within the walls of this temple of good-fellowship, Harvey's College. Louise Bourgeois was the first to describe prolapse of the umbilical cord, face presentation and its treatment, and expression of the placenta. She attended in her confinements Marie de Medici, wife of Henry IV. and mother of Henrietta Maria, the wife of Charles I., to whom individual entities; "constitutional diseases" occupy the stage, although this term has ceased to have a definite and exact meaning in modern pathology. Similarly, "heart diseases" and "renal diseases" are used in comparisons, as though each of these complexes had a single and simple, instead of a multifarious, causation. The constitutional factor and the organic fitness of the population are the subject of pseudo-learned disquisition, in happy ignorance of the elementary facts that the majority of so-called constitutional diseases—possibly all—are due to poisoning or infections derived ab extra, and that cardiac and arterial diseases, for instance, owe their origin chiefly to infections, of which syphilis and rheumatic fever are far and away the most important. Incidentally, although we may properly attach importance to the hygiene of middle life, and to periodical medical examinations as means to aid in preventing or in securing the early treatment of illness, it is well to bear in mind that the prevention of breakdown in early and late middle life is much more wrapped up with the prevention of the infections of childhood, of adolescence, and of early adult life than with any other factor that can be named. In substantiation of this statement I need only mention tuberculosis and syphilis, which together probably are responsible for one out of every five deaths from all causes at all ages in the aggregate.

[4] "De omnibus humani corporis interioribus membris anatomia," 1316. The first edition was published in 1596, and not 1601 as erroneously stated by Haller.

[5] Under Clement VI at Siena, during the plague in 1348, official necropsies were made to discover the cause of the disease. Curatulo, "L'arte di Juno Lucina in Roma," 1901.

4. It is unfortunate that in some states, including, I believe, Massachusetts, Ohio, and Michigan, the registration of births and deaths is not in charge of the Public Health Department of the State; and that ready access of each health officer to the vital statistics of his area may thus be a matter of grace, not of right, sometimes of belated grace.

5. As far as I can ascertain, it has not been found practicable to relegate institutional deaths to the vital statistics of the place of usual residence of the deceased. In England, Dr. Stevenson and I were able to organise a successful system by virtue of which the General Register Office in London has become a clearing house, and all deaths of non-residents, institutional as well as others, are referred to the area in which the deceased lived. Prior to this, curious errors occurred. An area in which a large maternity institution existed had a terrible infant mortality; and a city which prided itself on its low tuberculosis death-rate and ascribed this low mortality to its dispensary machinery, had its tuberculosis hospital for advanced cases outside the city boundary! To what extent such blunders occur in America, I cannot say. Its dimensions and population are probably too vast to admit of a federal system of relegation of deaths of outsiders; but it might be done for each state. In passing I would deprecate the imperfect correction for deaths of visitors which was commonly practised in England prior to the institution of the system I have indicated. Health officers very willingly excluded institutional deaths of visitors; but were less willing to add outside deaths belonging to their area!

6. In sickness registration I had the privilege of initiating one of the most valuable statistical reforms in England—viz., the weekly tabulation in the offices of the Local Government Board (now the Ministry of Health) of the number of cases of each of the notifiable infectious diseases in every one of the 1800 sanitary areas in England and Wales, and their publication and distribution within three or four days to every health officer. For some 14 years these have now been summarised in an annual return, thus presenting one of the most valuable epidemiological mines of information extant. The weekly returns of cases circulated from Washington by the Public Health Service are a step towards securing similar statistics in this country; and in this connexion should be mentioned the valuable relation established between the Federal and State Health Services by the appointment of officers of the latter as collaborating epidemiologists.

7. A striking lack in the vital statistics of the United States is with respect to housing accommodation. The decennial census returns in England enable the health officer to ascertain for all cities and larger areas the number of inhabited houses in each ward, the number of families living in one, two, three, four or more rooms, the number of rooms in each of these groups in which there are on an average more than two persons per room, and whether the overcrowding is of children or of adults. This information has important social significance.

8. I do not propose to discuss the difficulties which must obviously arise federally from having the responsibility for vital statistics divided between several Federal Departments; nor those which arise from the county control of collection of statistics in some states. I merely state the general proposition in which all familiar with the importance of the subject and the fundamental need for uniformity of method in securing data and in classifying the data when obtained will agree, that centralised administration on a large scale is essential if accurate and strictly comparable statistics are to be obtained. It is equally necessary that every health officer of every state, of every county, and of every city or smaller community should receive at least weekly full particulars of every birth and death occurring within his area, and should receive daily notifications of every case of infectious disease occurring within his area.

The preceding very imperfect review of the situation may be supplemented by some further suggestions—obvious, but none the less important—for making the statistics of each state and of every area within the state increasingly useful in the service of the community. Vital statistics are merely a means to an end. Their value consists in the light which they can throw on the prevalence of disease and on the means for diminishing its incidence.

Sanitary Indices of the Welfare of a Community.

I have not seen a State Public Health report in which the possibilities of utility of vital statistics have been fulfilled, although many such reports approach this goal, and still more contain much valuable material. It is necessary to bear in mind, however, that a heap of bricks does not constitute a house; and that undigested statistical matter should preferably be filed in the statistical bureau for further reference and treatment, and not presented in expensive and repellent tables to a public which is quite properly unsympathetic to such matter. There is need for detailed study of the vital statistics of every city and state, by men who have adequate medical knowledge, who can avoid the elementary pitfalls of statistics, and who above all are enthusiastically obsessed with the public health possibilities in the careful study of local statistics. In statistical work there has been, hitherto, too much shovelling into heaps, and too little building of the edifice of public health. No elaborate mathematical work is needed for the study which I am advocating, or for ordinary public health needs; but it is necessary that there be an observance of the well-known rules of statistical accuracy and of sound reasoning, based on scientifically established pathological and medical knowledge, and made with an enthusiastic desire to make statistics act as a pointer to the areas in which excessive mortality or sickness exists, in order that, an intensive study of its vital statistics having been secured, a corresponding social and sanitary investigation may follow and the appropriate remedy may be applied.

Such intensive studies are of special immediate importance in relation to the mortality of maternity, infant mortality, and mortality from tuberculosis. I am assuming that the sanitary index formed by typhoid fever and the important index of domestic cleanliness which the prevalence of infantile diarrhœa supplies, are kept constantly under supervision.

Together with these two, there are no more important indices of the welfare of a community than the three named above; and it ought to be practicable to state, year by year, for every area and every subdivision of an area—e.g., each ward of a city, the mortality associated with child-bearing, the total and the neo-natal infant mortality (i.e., under one year old and under one month old) in terms of births; and to take public health action in accordance with the findings. Hence the essential importance of complete birth registration. And it is not reassuring to find that in the year 1916 in the New England states there were no birth certificates in the case of 15 per cent. in Connecticut and 18 per cent. in Rhode Island, and of 5·7 per cent. in Vermont of the infants who died under the age of one year. Allowing for migration of infants from without each state, which must be small in amount, these figures cannot be regarded as satisfactory.

Selection of Health Work based on Statistical Study.

How much more effective would be the work of our public health nurses and at our health centres if the work were concentrated particularly on the infants in areas in which intensive statistical studies show that infant mortality is heaviest; and how much better directed and therefore more successful would be that work in the diminution of neo-natal mortality if every health officer had it forced on his attention that in some parts of his area the loss of life in the first month of extra-uterine life may be twice as heavy as in other parts; and if instead of futile observations as to the relative importance of "congenital debility," "prematurity," "marasmus," or the like in the death returns—which are mere labels of inexactitude of knowledge—and instead of theoretical and generally unfounded assumptions that deaths occurring at this tender age are unavoidable, assistance were given which would secure adequate care of the mother in pregnancy, in parturition, and during the critical first month after birth. It may of course be argued that unless we know the causes of this early infant mortality we cannot act intelligently against it. Such a statement illustrates well the difference between the armchair statistician and the competent physician engaged in public health work. The latter knows, for instance, that syphilis is responsible for a large share of this early infantile mortality, although it but seldom emerges in death certificates, and that its maleficent action on fœtal tissues can be prevented: He knows again that many of the fatal conditions, which cannot as yet be expressed in exact pathological terms, do not arise when appropriate medical, nursing, and domestic from Aubrey's statement that Harvey said, " he wrote philosophy like a Lord Chancellor, speaking in derision." Harvey gives another instance of his respect in the second part of his treatise when, after describing in great detail the development of the chicken (" all which hath perhaps been sufficiently prolix ") he writes: " hereupon (to use the expression of our most learned Verulamius) we shall proceed to our *second vintage*." He had a great admiration for the ancient writers, but said that only the ignorant will grant that they had " engrossed the whole truth." The neoteriques he called by an opprobrious name which even Aubrey was ashamed to print. He had little faith in " bookwrights, who conceive it plentifull satisfaction of minde to them that they finde it in Books and have their memories well loaded with sage sentences; for they that are thus philosophers ex traduce, by descent and derivation, are just as wise as their libraries." He appealed to observation of nature and experiment. His statement, " Nature herself must be our adviser; the path she chalks must be our walk," is an indication of the course he followed in his chapter on labour.

EMBRYOLOGICAL, GYNÆCOLOGICAL, AND OBSTETRICAL WORK OF HARVEY.

It is known to you all that Harvey was engaged during many years in almost daily observation and dissection of eggs and the uterus and embryo of animals and man. The results of his patient researches added greatly to our knowledge, and justify the remark of Frederick Ruysch that Harvey, " who is to be considered amongst the greatest of true philosophers," advanced the history of generation by his personal observations more than his predecessors by their united labours.[7] One pregnant generalisation, " ex ovo omnia " or " omnia animalia ex ovo," resulting from his researches is placed in the forefront of his " De Generatione Animalium," and it is, to use a favourite expression of Harvey, " strange " that a distinguished writer[8] should have failed to find the aphorism in the work, since " ex ovo omnia " appears on the remarkable frontispiece of the Latin edition published in London (with illustrations of the " animalia "), and on the second page appears the statement " omnia animalia ex . . . ovo." The mistake was probably due to the writer's having read one of the Amsterdam editions in which the plate does not bear the legend.

Harvey was a supporter of the doctrine of epigenesis as opposed to preformation of the embryo, and although he failed to discover the true nature of the ovum and regarded the uterus itself as an " exposed ovum," yet he is to be numbered amongst the " ovists " as opposed to the " animalculists " who were misled by incorrect observation with the compound microscope while Harvey formed a correct judgment based on accurate observations with the naked eye. Harvey had only the aid of a simple lens (" perspective ") to aid him in observing the minute changes occurring in the early stages of development; but the care he took is remarkable. He would place his specimens in water in a silver basin (no doubt to get reflected light) and took care to arrange for brilliant illumination of the object, as, for example, in his observation of the punctum saliens.

> " If you are desirous to make discovery of this observation towards the declining of the third day, you may, if you be extreamly intent, by the assistance of a clear and *great light*, or by the *Sun beams*, or a *Perspective*, make a shift to discerne it. For else this purple streak is so exceedingly nice and fine, and the motion of the *Punctum saliens* is so imperceptible, that you will only loose your labour."

As an admirer of careful observation in others, and as showing how remarkably the faculty of observation can be improved by practice, he gives instances of " a silly ignorant shepherd," who knew every sheep of his flock and the lambs belonging to each sheep; of hunters who can tell the state of the deer hunt in a wood from the various cries of their dogs; of others who can discover which eggs belonged to which hen. " I would," says Harvey, " we could as easily judge which son belongeth to which father."

HARVEY'S DESCRIPTIONS OF THE FŒTUS.

Harvey was the first to locate the origin of the embryo in the " cicatricula," and refuted Fabricius's opinion as to its origin in the chalazæ, the function of which as ligaments for the yolk Harvey was the first to discern. He showed by many direct observations and convincing arguments that the chalazæ had nothing to do with the embryo and casts a little ridicule on his master Fabricius's view in the words, " how improbable a thing is it that every egg should have two seeds or rudiments for the constitution of only one chicken." The bulk of Harvey's " Generation " consists in his careful observations and descriptions of the development of the ovum and fœtus in all stages in birds,[9] animals, and man. His remarkably accurate descriptions of the human fœtus make us regret that he did not employ the skill of his fellow traveller Hollar to illustrate them. He made many dissections of human embryos of almost all sizes " from the big-ness of a tadpole and so upwards to the birth." He calls attention to the great changes which take place in the second, third, and fourth months, and had often dissected the human ovum in the second month. It was of the size of a pheasant's egg; sometimes he found a fœtus, in others none. The fœtus was of the length of the nail of the little finger, but the shape was like a little frog save only that the head was great and the legs extremely short; just like the tadpoles in June. " The face was like that of other animals as of a dog or cat without lips and a wide mouth from one ear to the other." His description of the fœtus and its viscera at various ages commands our warmest admiration, both for its accuracy and happy illustration; thus of the fœtus at the third month " the substance of the heart was most white, having two ventricles of equal magnitude and thickness and a double *cone* like two twin-kernels of a nut; the liver was wondrous little and also white. All this time, namely for three months, scarce anything of the after-burden is to be seen." He points out how the head at first out-strips the body in bulk, but afterwards is very much short of it, that the like disparity is between the body and the limbs, so that at the second month his arms are so short that if you stretch out his fingers to their furthest extent they will not be able to touch one another, and his thighs are so short that being inflected upon his abdomen they will hardly reach to his navel. In new-born children the bulk of the body is a pretty deal larger than that of the limbs until they are able to stand and go. " But go upright they cannot till the prolixity of their legs and thighs exceeds the longitude of the rest of the body. And hence is it, that their first venture to foot it represents them a prone kind of cattell which can scarce exalt themselves to the erection of a cock."

Harvey made a discovery of the highest medico-legal importance when he observed that the lungs of fœtuses which had breathed " stretched and dilated by the air put on a whiter colour, and by this observation of the different complexion you may discover whether a mother brought her child alive or dead into the world; for instantly after inspiration the lungs change colour, which colour remains, though the fœtus die immediately after." The great and original merit of Harvey's work on generation lies in the careful and methodical observation and record of the embryo and fœtus at all stages. Harvey did for development what the illustrious Paduan professor, Malpighi, subsequently did for disease in his " De Sedibus et Causis Morborum " (1761).

HIS CONSIDERATION OF GENERATION.

When Harvey came to consider the causa causans of generation he confessed he was " at a stand." It

Harveian Oration

WILLIAM HARVEY OBSTETRIC PHYSICIAN AND GYNÆCOLOGIST

Delivered before the Royal College of Physicians on Oct 18th,

By HERBERT R SPENCER, M D, B S Lond,
F R C P Lond,
OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL

The Harveian orator is enjoined to commemorate past benefactors by name Linacre, Caius, Hamey, Lord Lumley, the Marquis of Dorchester de Mayerne, Croone, Goulston, Selden, and not least Harvey himself have by their gifts conferred enduring benefits on the College This year it is the duty of the orator to enrol amongst the list of benefactors an obstetric physician, the late Dr Lloyd Roberts of Manchester, who bequeathed a sum of £3,500 to the College and 1,800 medical books, including 50 "incunabula" and an almost complete set of the editions of "The Byrth of Mankynde," the first book on midwifery to be translated into English, which makes our College collection of this rare work the finest known In bequeathing these gifts Dr Lloyd Roberts has set an excellent example to other obstetric physicians, and I am but carrying out the injunction of Harvey in exhorting them to follow that example so that our College, whose immortal Fellow wrote the first original English work on midwifery, shall have in its library the best collection of books dealing with the functions and diseases of women Our distinguished Fellow Sir Thomas Browne alluded to the value of the College Library, but warned his correspondent against relying too much upon books—'ridiculous are they who think out of books to become physicians" He however, specially recommends the works of the Paduan teachers—Vesalius, Spigelius, Bartholinus, Fallopius, and Fabricius 'and be sure you make yourself master of Dr Harvey's piece, 'De Circul Sang.,' which discovery I prefer to that of Columbus' The other great work of Harvey was the 'De Generatione Animalium,' containing the chapter De Partu" It was the activity of anatomists in research on the female generative organs which aroused Harvey's interest in obstetrics and gynæcology, and in the year 1600 he went to study at the school of Padua, the city which had at that time the most distinguished University in Europe Thither flocked eager students, especially of medicine, to learn from the most celebrated teachers in the world

Padua had enjoyed profound peace since the siege of Maximilian in 1509, it was a healthy town, indeed a health resort, as it had been in the days of the Romans, when the aquæ Patavinæ were celebrated, it was also a very cheap place to live in, as testified by Montaigne in 1580 and Evelyn in 1646

From contemporary prints we can see what the University building—the 'Gymnasium omnium Disciplinarum"—was like The handsome façade of this Renaissance building was repaired during Harvey's student days, as we learn from a memorial tablet dated 1601 Over the gateway was the stemma of a Doge of Venice, and beneath it the Lion of St Mark Both these have since been taken down and replaced, to the detriment of the appearance of the building, by the Royal Arms of Italy There still remains, however, the legend 'Sic ingredere ut te ipso quotidie doctior evadas,' an injunction which Harvey faithfully obeyed (Fig 1) Passing through the gateway we come to the courtyard with its celebrated cloisters, in those cloisters were painted the "stemmata' of distinguished students, amongst them that of Gulielmus Harveius, a copy of which hangs in the College Library

Aubrey has given us the following portrait of Harvey in his younger days He was 'of the lowest stature, round faced, olivaster (like wainscott) complexion, little eie, round, very black, full of spirit his hair was black as a raven, but quite white 20 years before he dyed" "He was always very contemplative," writes Aubrey, 'and said he did delight to be in the dark as he could then best contemplate" He was indeed one of those of whom Cicero speaks quibus vivere est cogitare, and one can picture him deep in study in the cool and shadowy cloisters of the University, even as later he had caves made in the earth near his house at Combe in Surrey in which in summer time he delighted to meditate

The Paduan teachers Vesalius, Realdus Columbus, Hercules Saxonia, Casserius, Spigelius, and Falloppius all wrote works on obstetrics and gynæcology

Fabricius ab Acquapendente (1537–1619), who succeeded Falloppius at Padua, was Harvey's special teacher and "guide' He made many researches in comparative embryology He was of the opinion that the maternal vessels communicated with the fœtal, and that the fœtal heart had no influence on the circulation of the fœtus, no 'munus publicum," but beat only to preserve its own life He wrote 'Opera Anatomica quae Continent de Formato Fœtu, de Formatione ovi et Pulli, de Brutorum Loquela' which appeared at Padua in 1604 [1] He figured the decidua and the cord around the neck of the fœtus and studied the placenta in various animals Eloy says of him, "The degree of doctor of medicine with which he was honoured did not prevent him from publicly performing surgical operations" He taught for about 50 years at the school of Padua and died there universally regretted at the age of 82 He refused fees and put the presents his patients sent him into a cabinet labelled 'lucri neglecti lucrum" He built an anatomical theatre at Padua at his own expense, which generous act prompted the signory of Venice to build a much more spacious amphitheatre in his honour

Amongst other distinguished men of the Paduan school must be mentioned Mercurialis and Mercurius Mercurialis (1530–1606) was born at Forli in the Romagna in 1530, about ten years before Mercurius (Scipione Mercurio) with whom he is sometimes confounded He taught at Padua for 18 years, was created a Knight of St Mark, and amassed a fortune of 120,000 golden crowns His most celebrated work is "De Arte Gymnastica' (1569), but many works, including De Hominis Generatione" (1597) and "Monstrorum Historia Posthuma" (1642), were published by his pupils He wrote an important work "De Morbis Muliebribus," which was published in the collection of all the ancient and modern works on obstetrics and gynæcology entitled 'Gynæcia," the third and most complete edition of which was published by Israel Spachius in 1597, three years before Harvey went to Padua It is interesting to note that "La Comare' by Scipione Mercurio, which was published in the preceding year, is omitted from this collection

Mercurius ('Scipione Mercurio' [2] ? 1540–1616) was born in Rome and studied medicine at Bologna and Padua, but soon devoted himself to theological studies, and entered the Dominican monastery at Milan, where he took the name of Hieronymus He still continued to occupy himself with the study of medicine and, finding his monastic life did not afford him sufficient opportunities for the practice of medicine, he quitted the monastery and travelled in France and Spain in the years 1571 and 1572, as physician to a German officer, Hieronymus de Ladrone On completing this journey he returned to Italy, practised with great success in Padua, and settled in 1601 in Venice, where he lived for 15 years He wrote La Comare o Ricoglitrice," the first Italian work on midwifery It contains chapters and illustrations of Cæsarean section on the living patient, the uterus is palpable in the abdomen after delivery than that given by most modern text-books.

---

[1] Haller says it appeared in 1600

[2] *This is the usual form of the name, but in the first edition* it is printed Scipione Mercuri on the title-page of the first book Scipione Mercurio on the title pages of the second and third books

He shows his extensive experience by mentioning rare cases in his own practice, such as ectopic gestation, the passage of by-waters (hydrorrhœa) without premature labour ensuing, which "he had often seen," the survival of the infant which had been delivered by Cæsarean section several hours after the death of the mother, the child sucking the finger while still in the passage (? face presentation), the successful delivery of an unconscious woman (? eclampsia) by irritation of the nares; the removal of a putrid "false conception" (? sloughing fibroid) after delivery; the vagitus uterinus, &c.

Harvey has a special chapter on the membranes and humours of the uterus. With regard to the chorion, he points out the error of Fabricius in stating that the urine of the fœtus was passed through the allantois into the chorion and that the amnion contained the sweat of the fœtus, and asks if his master had ever seen such a creature as a sweating chicken. His own opinion was that the liquor amnii served as food for the fœtus. He based it upon the opening of the mouth of the fœtus seen through the membranes, the fact that the child will suck the finger while still stuck fast in the birth, and the way in which a new-born child sucks "as if he would devour the nipple; he still draws it into his mouth and by the aid of his tongue and palate he sucks the milk as if he chewed it; with farre more earnestness and delight than a grown body. Wherefore he seems to be good at it of old and to have practised it in the womb." Harvey also showed, as Arantius had done, that there was no communication between the vessels of the fœtus and the mother; the placenta "served to concoct or digest the alible nutriment which proceedeth from the parent to support the fœtus"; perhaps Harvey here anticipated the discovery of the function of the syncytium.

In considering the practical side of Harvey's work in obstetrics we are handicapped by the unfortunate loss of his "Medicinal Observations." In the management of ordinary labour he advocates patience and gentleness in imitation of Nature, which "is a perfect operatrix"; "if you carefully ponder Nature's works you shall find none of them made in vain; but all directed to some end and some good." He especially rebukes the "younger more giddy and officious midwives who, lest they should seem unskilful at their trade, do mightily bestirre themselves and provoke the expulsive faculty by medicinal potions whereby they rather retard and pervert it and make it an unnatural and difficult delivery and vainly persuading the women to their three-legged stoole weary them out and bring them in danger of their lives. It is much happier with poor women, and those that dare not own their great bellies where the midwives help is never required, for the longer they retain and retard the Birth, the easier and more successful proves the delivery." The birth in breech presentation is slow and painful, "and yet notwithstanding in abortment, and where the fœtus is dead or that there would be a hard delivery any other way, so that there is necessity of handiwork in the business, the more convenient way of comming forth is with the feet forward; for by that means the straights of the uterus are opened as it were by a wedge."

An excellent description is given of the contraction and involution of the uterus after labour, of the lochial discharge, of the after-pains, of the condition of the os as indicative of the state of the contents, of the powerful contraction of the uterus resulting from stimulant injections and the state of the lochia as a guide to treatment. He points out that if any clotted blood or any other preternatural matter remains in the cavity of the womb after delivery, the womb will neither retire upwards nor close its orifice, but its neck will continue soft and open, and mentions a case where, guided by this experience, he successfully removed an "almost gristly substance" (apparently a sloughing fibroid) as big as a goose's egg from a puerperal patient suffering from fever, a disordered pulse and a cold sweat "as if she were a-dying."

Harvey and Percivall Willughby.

Fortunately we are able to judge of the high esteem in which Harvey was held as an obstetric physician by the writing of his contemporary Percivall Willughby (1596–1685), who was the son of Sir Percival Willughby of Wollaton Hall, Nottinghamshire, and uncle of Francis Willughby the naturalist. He was educated at Tunbridge, Rugby, Eton, and Oxford, graduated B.A. on July 6th, 1621, and was admitted an extra Licentiate of the College of Physicians on February 20th, 1640. He practised in Derby from 1631 to 1655, when he removed to London for the better education of his children, returning in 1660 to Derby where (except for a short interval at Stafford) he practised up till his death at the advanced age of 89. He acquired a great reputation in midwifery throughout Derby and the neighbourhood, and wrote "Observations in Midwifery," and "The Country Midwife's Opusculum,"[10] which were first published in one volume in 1863, by H. Blenkinsop at Warwick, from a manuscript then in his possession, and now in the Library of the Royal Society of Medicine. Another manuscript was in the possession of Dr. Aveling. In this work, which gives the best contemporary account of midwifery in England, Willughby quotes his honoured friend Dr. Harvey on no less than 16 occasions, attributes all his knowledge to him and recommends his work in the following words, with which I will conclude: "I know none but Dr. Harvey's directions and method, the which I wish all midwives to observe and follow, and oft to read over and over again; and, in so doing, they will better observe, understand and remember the sayings and doings of that most worthy, good and learned Dr., whose memory ought to bee had for ever in great esteem with midwives and child-bearing women."

HUNGER-OSTEOMALACIA IN VIENNA, 1920.

I.—ITS RELATION TO DIET.*

By ELSIE J. DALYELL, M.B., CH.M. SYDNEY,
BEIT MEMORIAL FELLOW;
AND
HARRIETTE CHICK, D.Sc.,
LISTER INSTITUTE, LONDON.

A Report to the Accessory Food Factors Committee appointed jointly by the Lister Institute and the Medical Research Council.

Introductory.

TOWARDS the end of 1918 a condition with symptoms comparable to those of the earlier stages of osteomalacia was prevalent in Vienna. X ray photographs of some of the cases showed osteoporosis, and in a few instances spontaneous fracture occurred. The disease was described by Edelmann (1919), Schlesinger (1919, I. and II.), and Schiff (1919). Schlesinger pointed out that this disease to which he gave the name "hunger-osteomalacia" differed from osteomalacia associated with pregnancy in its slower development and more chronic character. Further, the pelvis was seldom affected, marked deformity was uncommon, and the majority of patients were elderly individuals of either sex. The disease occurred chiefly among the poorest section of the population, but many cases were noted also among middle-class people in reduced circumstances. All observers expressed the opinion that it was in some way connected with the food deprivation then existing in Vienna. In the late summer of 1919 there was a marked remission in the number of cases (Schiff, loc. cit.). Our investigations began in the autumn of the year 1919, and inquiries were first made in

---

[10] A Dutch translation of the "Opusculum" was published in 1642 at Leyden.

* The clinical observations contained in this paper were made by Dr. Dalyell.

Harvey makes many references in his work "De *Generatione Animalium.*"

The grievous practices of many of the midwives in England are given in great detail by Harvey's friend, Percivall Willughby. He writes: "When the meanest of the people were made priests in Jeroboam's days then Israel began to be afflicted; afterwards followed the destruction with the captivity of the people. When the meanest of the women not knowing how otherwise to live for the getting of a shilling or two to sustain their necessities become ignorant midwives, then travailing women suffer tortures by their halings and stretchings of their bodies, after which followeth the ruinating of their health and sometimes death." He goes on to give a testimonial in favour of the practice in London, where "the young midwives be trained seven years first under the old midwives before they be allowed to practice for themselves." In 1616, Peter Chamberlen II. made a petition to King James that some order might be settled by the State for the instruction and civil government of midwives; but nearly 300 years were to elapse before the desirable result was obtained through the persistent efforts of the Obstetrical Society of London (Midwives Act, 1902). In England the position of midwifery was degraded and the study of anatomy was in an inactive state when Harvey[6] went to Padua, where both subjects were being assiduously studied. The obstetrical and gynæcological writings of ancient and modern authors had just been published in the "Gynæcia"; the circulation of the blood, "the greatest physiological discovery of all times," was as yet unknown; the compound microscope had not been invented, and thus neither the ovum nor the spermatozoon could be seen. The ovary was still called the testis muliebris, but the ovarian follicles, although observed by Spigelius, were not well known till De Graaf published his observations in 1672; the spermatozoon was discovered by a medical student, Hamen, in 1675, as announced by Leeuwenhoek in the Philosophical Transactions in 1677. Thus when Harvey wrote the "Generation of Animals" he was dependent on naked-eye observation and experiment, and in reading this remarkable work one cannot help having a feeling of profound sympathy with the author and regret that the causa causans of generation should have escaped him solely because the compound microscope had not yet been invented, notwithstanding an amount of original research, faithful record, and close reasoning which has perhaps never been surpassed by a medical author.

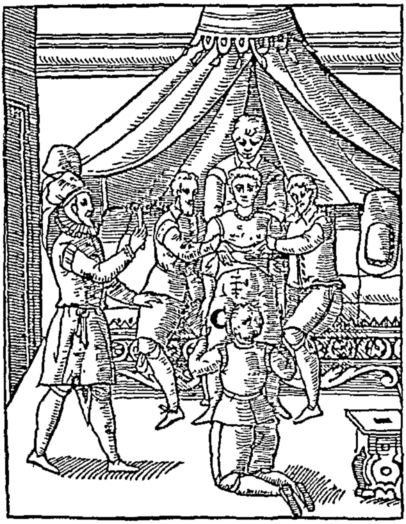

FIG. 2.—From the first edition (1596) of Scipione Mercurio's "La Comare"; Cæsarean section; the incision is to be made to the right of the middle line so as to avoid the spleen.

HARVEY'S BELIEF IN PERSONAL EXPERIMENT.

In the preface to the "Generatio Animalium" Harvey approves the opinion of Aristotle as to the necessity for observation and personal experience, and states that—

"No man can be truly called *prudent or knowing* who doth not by his own experience followed by manifold remembrance, frequent sensation and diligent observation know these things to be so. For without that we think only, or believe, and such knowledge as that is to be reputed other men's rather than our own. Wherefore fond and erroneous is that method of seeking truth in use in our times; while most men diligently enquire not what the truth is, but what other men say it is; and inferring universal conclusions from particular premisses and thence shaping to themselves irrational deductions they transmit to us things like truth for truth itself. Hence it is that sophisters and half-knowing men, polling other men's inventions, saucily impose them upon us for their own (shifting only the phrase and order and adding some impertinences of their own) and render Philosophy (which ought to be clear and perspicuous) obscure, intricate and confused. *For whoever they be that* read authors and do not by the aid of their own Senses abstract true representation of *the things themselves* (comprehended in the author's expressions) they do not resent true *Ideas*, but *deceitful Idols and Phantasms by which means* they frame to themselves certain *shadows* and *Chimaeras*, *and all their theory and contemplation* (which they count *Science*) represent nothing but *waking men's dreams* and *sick men's phrensies*."

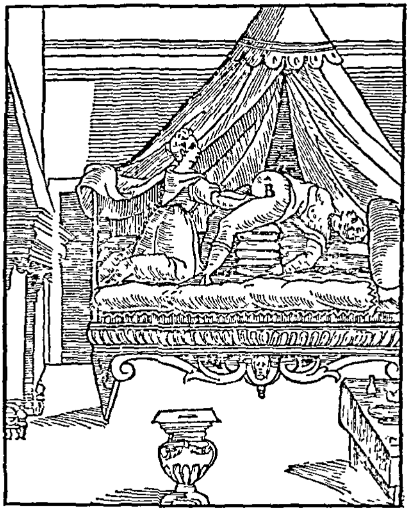

FIG. 3.—From the first edition (1596) of Scipione Mercurio's "La Comare," showing the "hanging-legs" position for delivery in cases of contracted pelvis.

In this and other passages defining his method of inquiry into the generation of animals, Harvey uses language very similar to that employed by Bacon, showing that he approved and adopted Bacon's method and did not assume a contemptuous attitude towards that great philosopher, as one might infer muscle groups—e.g., lumbar muscles, adductor muscles of the thigh, and the ilio-psoas. There was no opportunity for examining any histological specimens which might throw light on the process which took place at the painful sites, as we have no record of a fatal termination of any case of the disease that came under our observation. As far as we are aware the disease progressed until the patient was completely immobilised in bed, and succumbed ultimately to intercurrent disease (usually pulmonary) or to starvation, which unhappily was not an impossibility in Vienna in 1918–20.

---

[6] "Ex ea ipsa Anglia in qua hactenus anatome fere nulla fuerat exstitit novum artis lumen, cujus nomen ab ipso retro Hippocrate in medicina secundum est." Haller quoted by von Siebold, "Gesch. der Geb.," 1845, Vol. II., p. 246.

Occurrence of Tetany.

Occurrence of tetany with osteomalacia has frequently been noticed and is of much interest. In 22 cases of hunger-osteomalacia Schlesinger (1919, II.) observed marked tetany in two cases (elderly women of 62 and 55 years respectively), and extra excitability of the muscles in 15 cases. He calls attention to the facts (1) that tetany is otherwise a rare condition in elderly people, and (2) that in cases of "hunger-osteomalacia" accompanied by tetany, symptoms of the latter disappeared simultaneously with those of osteomalacia. In two instances a subsequent relapse was again accompanied by tetany. Schlesinger (1920) distinguishes this condition as "hunger-tetanie," and points out that the symptoms are often asymmetrical in their distribution. Sauer (1920) described the case of a woman, aged 29 years, suffering from marked tetany and simultaneously from severe hunger-osteomalacia.

Definite tetany was observed by us four times in a total of 39 cases, but many patients complained of some degree of cramp in the feet, legs, or forearms. The most marked case that came under our notice occurred in a woman of 52, suffering from severe hunger-osteomalacia (see Case 5 in Appendix), who showed altered electrical response of the muscles, Erb's sign, Trousseau's sign, and Schlesinger's sign (tonic spasm of the foot when the leg is flexed at the hip to a right angle). In every case seen by us the symptoms of tetany subsided gradually after the patient was admitted to hospital. Contrary to Schlesinger's observation that tetany and osteomalacia symptoms were relieved simultaneously, in the case mentioned above (Appendix, Case 5), the tetany manifestations were greatly relieved before the treatment had shown much effect upon the osteomalacia symptoms.

Age- and Sex-Incidence.

Hunger-osteomalacia may be regarded as a disease which affects specially the portion of the population above middle age. Hume and Nirenstein's (1921) analysis of 131 cases treated as out-patients at the Zentral Verband der Krankenkassen shows that 115 (or 88 per cent.) were between the ages of 40 and 75 and 16 (or 12 per cent.) were under 40 years of age. Our notes of 43 cases show 36 (or 84 per cent.) between 40 and 70 years of age, and 7 (or 16 per cent.) between 20 and 40. Of 19 cases of hunger-osteomalacia studied by Edelmann (loc. cit.) in 1918 to 1919, 15 were women and 4 were men. In the cases observed by us in 1920 there was also a much higher proportion of women than men, but these included cases in convents. In the general population in 1920 the numbers of men and women affected were more nearly equal. Of 177 cases in which sex was noted by Hume and Nirenstein 99 (or 56 per cent.) were women and 78 (or 44 per cent.) were men. In this outbreak of hunger-osteomalacia, as compared with the better known osteomalacia of pregnancy, the most striking features were the incidence among elderly and old people, and the extent to which men were affected.

Influence of Occupation.

Evidence was not obtained to show that hard manual labour was a special contributory cause of hunger-osteomalacia. If the condition results from food deprivation, analogy with other deficiency diseases suggests that a relation would exist between the incidence of the disease and increased physical strain. Age, however, had more influence than occupation in determining the incidence of hunger-osteomalacia, and the hardest manual work was performed by individuals of an age (20–40) when some degree of protection from the condition seems to be afforded naturally. Moreover, in the existing economic crisis artisans and manual labourers were better paid and could secure a more abundant supply of food than other sections of the population, so that this additional advantage helped to protect such workers. Poverty and old age predisposed to the disease, and in many cases the food deprivation was specially severe and prolonged. In the convents the dietary was rigidly reduced, due partly to poverty and partly to the isolation in which these communities were placed. The lack of food was so extreme that younger occupants of the convents suffered as severely from the disease as the older nuns, and sisters appointed for light teaching duty were as much affected as those responsible for gardening and heavy household tasks.

Seasonal Incidence.

The seasonal incidence of hunger-osteomalacia was interesting. Many recurrent cases gave a history of first appearance of symptoms in winter 1918 or early spring 1919, with remissions in summer 1919 and relapse in the winter of 1919–20. The fresh cases seen by us had begun to suffer in the cold weather of the late autumn of 1919. The relief experienced in summer weather was probably due to higher temperature, but it is also possible that the disease was alleviated as a result of the improved diet associated with the summer season.

Ætiology.

The literature is full of observations, connecting osteomalacia and other disorders affecting the calcification of the bones with the activities of the ductless glands. A comprehensive abstract of the papers upon this subject is given by Zuntz (1912). Important observations in this field are those of Erdheim (1906) who, after extirpation by cautery of the parathyroids, produced a condition of tetany in rats, as well as abnormal dentine formation. Later (1914) the same observer found abnormal histological conditions in the parathyroids in a series of rats which developed rickets spontaneously. In addition (1907) he found at autopsy pathological changes in the parathyroids of human subjects who had suffered from osteomalacia of pregnancy. The theory advanced by Erdheim is that the normal secretion from the healthy parathyroid may have neutralising effect upon that of other glands, such as the ovary, which may, in certain conditions, affect the normal course of bone formation. Some support for this view is found in the association of osteomalacia with multiple pregnancy (Sonntag) and in the beneficial effect of castration upon such cases as described by Fehling (1891; 1895). Other observers have recorded the good effect of treating osteomalacia with adrenalin (Bossi (1907), Edelmann, loc. cit.); and extract of the hypophysis was employed with good effect in osteomalacia by Bab (1911), Neu (1911), Pal (1912), and in rickets by Klotz (1912). Biedl (1916) reached the opinion that the cause of osteomalacia is to be found in the disordered action of more than one gland.

It has been well recognised also that external conditions have an influence upon the incidence of osteomalacia. Sonntag (1905) states that although everywhere a rare disease it is unusually frequent in certain places, such as the valley of the Rhine and its tributaries, Lombardy, the Danube Island Schütt in Hungary, and the Harz Mountains. The disease is comparatively rare in North Germany, in the United States, and in England, where it is described only in association with pregnancy. Sonntag also connects the occurrence of the disease in pregnancy with damp dwellings, poor diet, insufficient clothing, hard work, and excessive care and worry, in a word with poverty, and he calls was a "dark, obscure business" about which "authors do nowhere more cavil and contend" Having failed, owing to the non-existence of the compound microscope, to discover the ovum or the spermatozoon, and having convinced himself by many observations and experiments that no part of the male seed entered the uterus, "and yet there is a necessity that something should be there which may render the female fruitful," he had no refuge left but to apprehend that the woman was impregnated by the conception of a general immaterial idea, "that the same thing is effected in the womb as in the braine, unless," he adds, "some cunning Philosopher whom the gods have better provided for can finde out some efficient cause which is not included in our recapitulation" Atoms, contagion, effluvia, odours, incorporeal spirits had all been cited as the efficient cause · Harvey pleads for a place for his conjecture which he offers "in a problematical way" until there be some certainty established in the business "Let the learned and ingenious stock of men consider it; let the supercilious reject it; and for the scoffing ticklish generation, let them laugh their swinge" The whole of the work on the development of the fœtus is a testimony to his great powers of observation and reasoning, and justifies Sir Thomas Browne's description of Harvey as an "ocular philosopher and singular discloser of truth," and his work as that excellent discourse of generation so strongly erected upon the two great pillars of truth, experience and solid reason"

GYNÆCOLOGY

Gynæcology in Harvey's time was in an *embryonic* state of development Since Moschion wrote his Περι των γυναικειων Παθων it has taken its place in practice by the side of midwifery, an association which it should always retain. Harvey made several notable contributions to this branch of medicine He gives a good description of the broad ligament of the uterus—"*the pendulous band or tie*" *he calls it*, *mentions* the Hottentot apron of which he received information from a surgical friend, "an honest man": this he likens to the "vail" in animals He describes the green sickness in virgins "whose womb is slender and their terms are at a stay"; had seen ectopic gestation; alludes to the displacement of the womb, is doubtful as to the agitation of the womb in hysteria, the discovery of the truth of which "as it is very difficult so it is worthy the attempt" He gives a good account of spurious pregnancy and mentions an instance in a noble matron whom, in spite of all the arguments he could suggest, he was unable to persuade that she was mistaken; this shows a considerable experience and confidence in diagnosis

Harvey applied his knowledge of the circulation of the blood to surgery, pointed out how by tying the artery going to a tumour the tumour could be removed with safety, *and thus laid the scientific foundation for* the extensive operations, such as hysterectomy, now performed by the same method (isolated ligation of vessels instead of ligation en masse) a lesson not yet learned by all gynæcologists at the present day. In the treatment of intra uterine diseases Harvey invented a dilator, after which he used injections and by this means cured patients suffering from offensive discharges and from sterility. Harvey discovered a peculiar bleeding tumour of the uterus which he called the "honey-comb"; for the mention of which we are indebted to the "Observations in Midwifery" of his friend, Dr Percivall Willughby. When we recall that we owe to Ent the publication of the "De Generatione Animalium" we can only surmise how many other observations of Harvey's were contained in his lost "Medicinal Observations" to which Harvey often refers. Willughby writes —

> "*There came into my house at Darby, my honoured good friend Dr Harvey 1642 Wee were talking of severall infirmities, incident to the womb After that I had related the aforegoing story de cauda mulieris, and how shee flouded, and was cured, hee added to my knowledge an infirmity, which hee had seen in women, and hee gave it the name of a honey comb, which also, hee said, would cause flouding in women*"

No further details are given; but the appellation "honey comb" suggests that the growth had holes in it discharging thick fluid *so far as I know* the only condition of the cervix corresponding with this description is a very rare form of cancer of the cervix, an instance of which has been published, with illustration, in the Lettsomian Lectures for 1920 Percivall Willughby was at the time of Harvey's visit 60 years of age and was well acquainted with the ordinary forms of cancer, of which he records many observations It is interesting therefore to find that Harvey should be able to add to the knowledge of this experienced gynæcologist an undescribed disease, the "honey-comb."

MIDWIFERY.

Harvey's Chapter on Labour ("De partu"), the first original English work on midwifery, justifies Aveling's designation of Harvey as the father of British midwifery The scientific part of the work consists in criticism of previous opinions on the anatomy and physiology of the fœtus and of parturition based on his own observations, the practical part gives evidence of extensive personal experience in midwifery and is in the main devoted to the recommendation of patient watchfulness and gentleness, imitating nature, in ordinary cases, and podalic version in difficult ones

Harvey was the *first to describe accurately* the fœtal circulation and the great development of vessels in the pregnant uterus He also had observed, as *Ambroise Paré had done before him*, the *softening* and loosening of the sacro iliac and pubic articulations before labour. He gives a careful description of the lie *and posture of the fœtus in utero, states that* it executes the somersault ("dives down") a little before labour and that it sometimes changes its *presentation from time to time* "*For he swimmeth* in a water and moveth himself to and fro, he stretcheth himself now this way, and now that, and so is variously *inflected and tumbled up and down, in so much that* sometimes, being entangled in his own navel string, he is strangely ensnared"; "and the Great-bellied women know full well that he doth *sometimes acquire* a different scituation when they find the Child kick sometimes above, sometimes below, and now on this side and at other times on that" With regard to the duration of pregnancy, he gives the usual ten lunar months He quotes Franciscus Valesius's case *of the survival of a five months' girl and another case* of a woman who bore a living child after a gestation lasting 16 months "But I confess," says Harvey, "*these are rare accidents*" "It must not be denied that there are many crafty and fraudulent women which for lucre sake, or for fear of punishment or infamy will feign and swear they are with child. And likewise it is well known that others are easily deceived and do conceive themselves to be with child when it is no such thing" And *a* superfœtation may cause the duration of pregnancy to be apparently longer than it is in fact He alludes to cases in which the fœtus is born completely enclosed in the unruptured membranes, and cases of adherent placenta "oftentimes hardly divided from the uterus which doth induce evil symptoms, noisome smells, and sometimes gangreen whereby the mother is brought into imminent danger"

Harvey shared the opinion of Hippocrates that the birth of the child was due in the main to its own efforts, and here is at variance with Fabricius, who ascribed the work to the uterus, the muscles of the abdomen, and the diaphragm. Harvey admits, however, that the uterus has its share in the business, and gives details of a case of labour in a procident uterus as a proof, and states that an unnatural birth sometimes results from failure of the mother in her expulsive office (uterine inertia) Harvey gives a careful description of the involution of the uterus after delivery and of the lochial discharge "It is indeed a wonderful thing that the so vast bulk of the uterus should so much lessen in so short a space, namely, in the space of 15 or 20 days" This is a more accurate statement of the period during which use of phosphorus in the form of pills without oil (Schlesinger, 1919, I.); this treatment, however, was not tried with out-patients, but coincided with admission to hospital and a generally improved dietary. A similar criticism applies to the good results from the use of extract of thyroid gland reported by Edelmann (loc. cit.).

In view of the possible connexion between the known high content of cod-liver oil in fat-soluble A accessory factor, and the efficacy of the oil in the treatment of osteomalacia, it was desirable to try to determine the therapeutic value, in this disease, of various fats known to contain the fat-soluble A accessory factor in different degree. The results obtained are set out in detail below. They show that the symptoms could be relieved, in absence of any other treatment, by one each of the series of fats employed, but that cod-liver oil was the most potent. Zilva and Miura (1921) have succeeded in making quantitative estimations of the relative content of A vitamin in different fats, and in experiments with rats have found some samples of cod-liver oil to be 250 times as potent as butter.

TABLE I.—*21 Cases of Osteomalacia in Convents.*

The additions to the diet were arranged to be approximately equal in calorie value.

Group.	Addition to diet.	Approx. amount daily, g.	Calories.	Fat per day, g.	No. of cases.	Result.
(*a*)	Sugar or syrup. Cereal. Olive oil.	15 40 15	330	15	10	Good progress in 5 slight cases; no progress in 5‡.
(*b*)	Margarine.* Olive oil.	25 20	380	43	5	Good progress slightly inferior to (*c*).
(*c*)	Butter. Cod-liver oil. Egg (dried).	25 10 =1 egg	360	40	11†	Good progress.

* This sample of margarine was believed to be manufactured from vegetable fats, it has since been ascertained that it contained 80 per cent. animal fats.

† Later including 5 from group (*a*).

‡ Three of the 5 cases in which no progress was made were severe, and showed good improvement when treatment (*c*) was substituted.

TABLE II.—*18 Severe Cases of Osteomalacia.*

Observations taken in the III. Medizinische Abteilung at the Allgemeines Krankenhaus (Prof. Dr. H. Schlesinger), February–April, 1920. The effect of various additions to the ordinary hospital diet.

(*a*)	Sugar or syrup. Rice or other cereal.	60 100	550	0	5	See below (1).
(*b*)	Margarine.* Olive oil.	50 (25 at first.) 15	540	60	13	Steady progress in 8 cases; very slow progress in 5.
(*c*)	Butter. Egg (dried).	50 (25 at first.) =1 egg	400	52		
(*d*)	Cod-liver oil.	60	540	60	4	See below (2).

(1) Very slow improvement in 20–30 days; marked progress when changed to (*b*), (*c*), (*d*).

(2) Marked improvement in 4 severe cases, making slow progress on (*a*), (*b*), and (*c*).

The food supplies of Vienna in general were most irregular, and it was not possible to arrange special diets which could be controlled in every particular. Except for a few important cases we had to be content with watching the effects of various additions to the ordinary diet, whether in hospital, convent, or home. Without exception such ordinary diets were always deficient in fat and always scanty. The following foods were, therefore, chosen for the different groups into which the patients were divided, and in comparative observations the additions made were roughly equivalent in calorie value. (*a*) Sugar and cereals; (*b*) vegetable oils (margarine, olive oil, &c.); (*c*) butter and eggs; (*d*) cod-liver oil; (*e*) vegetable oil containing phosphorus; (*f*) green vegetables. After admission to hospital some improvement usually followed from rest in bed, and relief from the misery caused by moving about, but such effects were only temporary, and relapse occurred if no increase were made in the fat-content of the dietary. (Tables I. and II.)

(*a*) *Influence of Sugar and Cereals—i.e., extra calories without extra fat.*—These additions were made to the ordinary hospital diet of five severe cases in the Allgemeines Krankenhaus (see Table II.). Slow improvement was noted in three to four weeks, but only one case progressed sufficiently to leave hospital; the other four cases required a further period with treatment by addition of (*b*), (*c*), or (*d*) before they could be discharged (e.g., Case 2 in the Appendix). Ten cases in a convent (see Table I.) also had their diets enriched with extra cereals and sugar, but here a small amount of olive oil (15 c.cm. daily) was also added. Progress was noted in five of the lighter cases only, and not in the remaining patients. (Table I., group (*a*).)

(*b*) *Influence of Vegetable Fats and* (*c*) *Butter and Eggs.*—The treatment of a series of cases with these additions was arranged (see Tables I. and II.) in the belief that the ordinary vegetable oils of commerce might be regarded as free of the fat-soluble accessory factor, a view in accord with results obtained by McCollum and by Osborne and Mendel and their co-workers (loc. cit.). Such additions would therefore have demonstrated the effect of adding fat to the diet uncomplicated by the presence of the vitamin. We found, however, that the effect of vegetable fats differed only in degree from that of butter and cod-liver oil, since cures followed the use of each of the fats administered, but when vegetable oils were used, the good effect appeared more slowly and in severe cases was less complete. (See Case 1 in Appendix.) The margarine employed was selected in the belief that it contained only vegetable oil, but on subsequent inquiry from the manufacturers it proved to contain 80 per cent. of animal fats. No marked difference was observed in the response to treatment of 24 cases divided into two groups, one of which received margarine and olive oil, and the other butter and egg as dietetic additions. (See Tables I. and II., groups (*b*) and (*c*).)

(*d*) *Cod-liver Oil.*—This was the most effective fat tried, and no case failed to recover when this oil was added to the dietary in sufficient amount. Doses of cod-liver oil equal to 60 g. daily effected speedy cure in severe refractory cases after other forms of treatment had failed. Cases 5, 6, 7 in the Appendix are instructive instances.

Case 6, George R., aged 60, was specially severe, suffering acute pain with the least movement. As additions to the hospital diet, he received margarine and olive oil in amounts equal to 65 g. of fat daily for 40 days, but no definite change took place in his condition. 30 g. of cod-liver oil daily were then given for seven days, and were not effective; but on increasing the daily dose to 60 g. cod-liver oil there was a dramatic improvement in his symptoms within a week, and in three weeks his gait was easy and painless. This case illustrates well the necessity for giving the requisite amount of the right sort of fat.

Case 7, Christina B., was the most severe case encountered. She had been unable to walk for three months before entering hospital, could not stand without support, and was helpless except for slight movements in bed made with the help of her hands. In addition to the ordinary hospital diet she received at first 25 g. and later 50 g. of butter and one egg each day for 31 days, and for part of this time phosphorus pills were also given. At the end of this period scarcely any improvement was noticeable. After changing her extra allowance to 60 g. of cod-liver oil daily, marked progress was evident after five days and the patient was discharged after 14 days of this treatment.

One very refractory case was that of Mater U. (Case 4, Appendix), a delicate woman, aged 52, who could not tolerate cod-liver oil. Treatment for 17 days with 20 g. butter daily, plus extra milk and eggs, was very disappointing, but after increasing the butter ration to 50 g. daily and the milk to ½ litre, there was slow steady improvement and the patient was able to walk without her stick after 10 days. Another severe case in the same convent (Mater P., aged 57, Appendix, Case 3) treated at the same period with 20 g. butter daily and with 15 g. cod-liver oil instead of milk or eggs, made rapid progress and admitted immediate relief from pain.

(*e*) *Influence of Vegetable Oil to which Phosphorus was added.*—Miss Hume and Dr. Nirenstein made a special series of investigations to determine the comparative value of cod-liver oil and of vegetable oil containing phosphorus with 131 out-patient cases selected from about 500 at the central station of the Verband der Krankenkassen. A detailed analysis of these observations is published by the

October and November, regarding the occurrence of the disease, but no cases were found In December, however, fresh and recurrent cases were seen in two convents in which the nuns had suffered severely during the previous winter, and simultaneously there appeared in the hospitals, both as out patients and in patients, persons suffering from the disease in various degrees of severity From this date until the late spring of 1920 there was no lack of material for study

By arrangement with Prof Dr Arthur Schiff, investigations were undertaken in his out patient department at the Central Verband der Krankassen, one of the principal medical centres of the Health Insurance Organisation in Vienna At this centre medical examination took place of all persons applying for sick pay through inability to work Between January, 1920, and May, 1920, over 600 patients diagnosed as cases of hunger osteomalacia attended for medical advice, of these 204 were selected for special study. These patients attended regularly for examination and special treatment, and observations were made of their progress by Miss M Hume in collaboration with Dr E Nirenstein A detailed account of this investigation is published in a separate paper

In addition to the ambulatory cases in convents and at the Krankenkassa, special observations were made on 18 cases admitted to the III Medizinisches Klinik of the Allgemeines Krankenhaus by permission of Prof Dr H Schlesinger, and upon eight cases in the I Med. Klinik of the University (Prof K F. Wenckebach), in collaboration with Dozent Dr Porges

Onset, Symptoms, and Course of the Disease

The short description of hunger osteomalacia symptoms given by Schlesinger and Edelmann has reference to severe cases admitted to hospital as in patients In these the painful areas were commonly the chest and the sacral region the ribs were invariably sensitive to pressure, and less often pain was felt in the extremities Bones of the face were affected in about one third of the cases, the pelvis was rarely painful, and pelvic deformity was not observed There was great pain on movement, and in cases not completely bedridden there was a characteristic stiff and waddling gait, and the climbing of stairs was specially difficult Frequently the patients declared that they had decreased in height Edelmann described the condition of his *patients as prematurely aged*

The variety of material that was available allowed *our observations on the disease to be made at all* stages of its course.

The initial symptom was difficulty in walking owing to pain in the tarsal and metatarsal bones, generally accompanied by œdema of the feet and ankles The œdema when present subsided after some weeks, but without diminution of pain on walking The lumbar and sacral regions were next affected and stooping or walking was accompanied by severe pain in these areas, of an intense and persistent nature Thoracic symptoms developed later with pain on compression of the ribs, progressing from lower to upper ribs, pain was often felt also on coughing or deep breathing Arms, shoulders, and hands were not so often affected, and face symptoms were present only in the most severe cases

The disease was afebrile, and progressed from the early condition with mere discomfort in walking to a bedridden state in which any movement of the body caused agonising pain The following description applies to the ambulatory cases of moderate severity which came most commonly under observation The patient had a characteristic expression the face sallow, the eyes sunken and with an expression of suffering The skin was dry, harsh, and loose, the body anæmic, flabby, and ill nourished, but not usually emaciated Movement was painful, and in walking the body was bent forward and, as a rule, support of a stick in one or both hands was necessary The waddling gait and the difficulty in mounting steps were so characteristic that it was easy to detect sufferers from the disease among the people in the street, especially when endeavouring to enter trams or vehicles The legs were widely spaced, the feet hardly lifted from the ground in short shuffling steps, and the body moved stiffly from side to side in the endeavour to limit as much as possible swinging movement at the hips *Attempts to step upwards, as in* mounting stairs, failed unless a support could be grasped with the hands and the body pulled up by the shoulder muscles The pains were always associated with movement As long as the patient could remain motionless whether lying, sitting or standing there was little discomfort, but movements in which the trunk muscles were involved, as in bending, turning, sitting up or walking, caused acute pain which was always worse with the preliminary muscular effort

The hands arms and shoulders, being seldom affected, were much used in carrying out movements Thus the patient would change from lying to sitting, or from sitting to standing, with the help of arms and hands, and in a severe case would get in or out of bed only after flexing the legs by lifting the thighs with the hands over the edge of the bed The defective action of the body muscles was not due *to loss of power, but to voluntary limitation of movement* owing to apprehension of pain Many movements only *became painful when pressure or weight was exerted on the* parts concerned For example if the patient could support the body by grasping a fixed object with the hands, the foot could be lifted from the floor and the leg flexed at the hip *and knee without obvious discomfort, but a similar move*ment to carry the body up a step was often impossible, *from the severe pain produced by throwing the weight of* the body on one side of the pelvis

Systematic examination of patients showed certain areas where manual pressure was almost invariably painful Such *pressure points were always over bones* The joints were rarely involved and muscular masses were never sensitive *The tarsal bones, especially the head of the astragalus and* the proximal ends of the metatarsals, were usually sensitive, *also the lower ends of the tibia and fibula, and the anterior* and inner borders of the tibia in its lower half, the lower *two thirds of the shaft of the femur was occasionally sensi*tive The knee joint was rarely involved and the hip joint was always free *from pain* The *most sensitive pressure area* was the sacral and lumbar region—e g, over the sacro iliac joints and transverse *processes of* the lumbar vertebræ Severe pain was always felt in this area during stooping *or bending movements, and this symptom was always* marked and persistent The iliac crests, pubic rami, and *pubic symphysis were seldom affected, and deep pressure* through the abdominal wall on the inner surface of the *ilium was never painful Bony deformity of the pelvis did* not occur in any case seen by us

Sudden abduction of the flexed thighs usually *caused* severe pain over the lesser trochanter and at the site of the *insertion of the adductor muscles, a symptom attributed to* sudden tension of the ilio psoas and adductor muscles This formed one of the chief diagnostic features of the disease and was an important indication of its progress or remission.

In almost every case, sudden *compression of the ribs* caused acute pain, felt most severely in the axillary line The lower four ribs were commonly affected, in severer cases the fourth–eighth ribs also, and the upper ribs were rarely involved Here also the pain was evidently associated with tension of the intercostal muscles The thoracic vertebræ *and posterior rib junctions were not sensitive nor were the* costochrondal junctions and costal cartilages Pressure on the sternum sometimes caused pain but it was not often severe The bones of the face were sensitive only in certain advanced cases and this symptom yielded readily to treatment When present the painful pressure points were over the supra orbital ridges, malar bones, nasal bones, and along the mandible

The muscles were not painful when handled, showed neither wasting nor other deformity, and their contractile force was not diminished It was therefore unlikely that the whole muscle was involved in the existing lesion The nerve reflexes were normal, and there was no evidence of peripheral neuritis nor of damage to nerve trunks so that it was improbable that the symptoms of the disease could be due to nerve involvement only The association of tetany with the disease was not infrequent This is a point of special interest and is dealt with in a later section

The degree to which bones were involved in the lesion was difficult to determine The sensitive areas were limited Bony deformity was not seen by us but has been described by Eisler (1919), Eisler and Hass (1921), and Schlesinger In their observations the affected areas included ribs, pelvis, spinal column and femur Evidence of a pathological change in the substance of the bones was obtained by us from a few patients who gave definite history of decrease in the height of the body (cf Schlesinger, 1919, I, and Case 1 in Appendix) In one instance also spontaneous fracture of the femur occurred in a woman aged 32 *Spontaneous fractures were observed by Edelmann also* (loc cit)

Although it was not possible to say with certainty how much of the bone substance was *affected*, it was evident that the areas of acute pain on pressure corresponded to the points of attachment of certain ribs, lumbar vertebræ, and sacro-iliac joints; has pre-tibial œdema and when trying to walk has cramps in both feet.

Treatment.—(*a*) Extra calories, consisting of cereals and carbohydrates with 15 g. daily of olive oil. After 16 days' treatment, no improvement. (*b*) Butter 25 g., cod-liver oil 15 g., and one egg given as additions to the daily diet. After eight days' treatment, improvement in pressure pains and in body movements; walking somewhat less painful. Twenty-three days: can walk rapidly without use of stick; movements of body free and painless; no pains on pressure over ribs or sacrum; some pain and œdema persist in feet. General condition greatly improved; prophylactic doses of cod-liver oil continued.

CASE 4.—Mater U., aged 52; treated from Jan. 10th, 1920, in convent. Symptoms have been present for two years and are specially severe. Patient emaciated, and gives definite history of decrease in height and shortening of arms. Walking and all body movements cause intense suffering, and pressure pains are acute over ribs, sacro-iliac joints, lumbar vertebræ, hip-joints, dorsum of foot, and calf muscles. Has tendency to spasm of foot.

Treatment.—(*a*) Extra calories as for Case 3. After 14 days' treatment, no improvement. (*b*) Butter 25 g. and one egg daily, in addition to ordinary diet; cod-liver oil 15 g. daily was also ordered, but could not be tolerated by this patient and was not taken. After 17 days' treatment, no improvement. (*c*) Butter 50 g., one egg, and 250 c.cm. milk daily in addition to the ordinary diet; total extra fat 60 g. After 14 days' treatment: marked improvement; slight pressure pains persist over sacrum and lower ribs, but not elsewhere; gait still stiff, but walking is no longer painful and for four days patient has not used her stick; body movements in bending, sitting, or standing still limited but greatly improved. Prophylactic treatment continued with smaller doses of butter and milk daily.

CASE 5.—Maria B., aged 62; admitted Jan. 13th, 1920. A severe and refractory case, complicated by tetany. Symptoms have been present for past year in ribs and sacral region. For some months patient has been unable to walk owing to pain caused by body movement and has remained in bed; she can turn in bed and raise herself only with great difficulty and with use of hands. Tetany well marked; Trousseau's sign and Erb's sign positive.

Treatment.—(*a*) Extra calories in form of cereals and carbohydrates; anti-neuritic vitamin also given as marmite, 10 g. daily. After 10 days' treatment: no change in general condition; all symptoms still present, and tetany well marked. (*b*) Butter 25 g., one egg and marmite 10 g. daily in addition to ordinary hospital diet. After 10 days' treatment: no improvement; patient is unable to walk, and pressure pains are unchanged; tetany symptoms are less marked but still present. Since admission increase in body-weight of 2·4 kg. (*c*) Cod-liver oil 60 g. daily. After 10 days' treatment: marked progress; can walk a little and gets in and out of bed without difficulty; great diminution in pain on compression of ribs and on abduction of thighs; knees still painful and slight ankle-clonus present; tetany symptoms much less marked. Twenty-one days: pressure pains persist though slighter in degree; abduction test negative; gait still stiff. Thirty-five days: pressure pains have disappeared; no abnormality of gait, and patient walks slowly without pain; complains only of pain in ankle-joint and along shaft of femur on right side. Discharged March 15th, 1920.

CASE 6.—George R., aged 60; admitted Jan. 14th, 1920. Body-weight 58·5 kg., height 171 cm. Very severe case, with history of onset of symptoms nine months previously. First noticed œdema of legs and pains in ankles; thighs and ribs were later affected. All movements are so painful that patient is now practically helpless; cannot stand without support, and in bed can change position only by use of hands and arms. Has acute pain on compression of ribs and sternum, and on abduction of flexed thighs.

Treatment.—(*a*) Extra margarine 25–50 g., olive oil 15 g. daily, in addition to hospital diet. After 25 days' treatment: margarine 25 g. daily, no improvement. Margarine then increased to 50 g. daily for a period of 10 days; slight improvement, but still unable to walk. (*b*) Cod-liver oil 30 g. daily, later 60 g. After two days' treatment: immediate diminution in pressure pains; rib symptoms less marked; walking no easier. Seven days: rib symptoms almost disappeared; still cannot stand without support; cod-liver oil then increased to 60 g. daily. Fourteen days: pressure pains and abduction pain very slight: can walk slowly without support and with little pain. Twenty-one days: condition very satisfactory; walks well and makes free movements of bending, sitting, and standing. Twenty-eight days: traces only of pressure pains elicited; gait normal and patient walks without pain or fatigue. The general condition is very good and weight has increased 9 kg. since admission to hospital. Discharged March 22nd, 1920.

CASE 7.—Christina B., aged 50; admitted Feb. 5th, 1920. The most severe case that came under our notice. Symptoms have been present without remission since previous spring, and for four months before admission patient has been helpless in bed. Pressure pains over ribs, sternum, pelvis, and lumbo-sacral region are intense, and acute pain follows abduction of flexed thighs. Patient stands feebly when supported, but cannot take a step nor carry out any body movement owing to the agonising pain that accompanies muscular effort.

Treatment.—(*a*) Butter 50 g. and one egg daily, in addition to ordinary hospital diet. After 14 days' treatment: patient is freer from pain, can sit up in bed slowly and get in and out of bed with difficulty; cannot walk. From this date phosphorus pills given, equivalent to 0·0005 g. phosphorus daily. Twenty-five days: no progress in movements and condition still very helpless; pressure pains still acute, especially in ribs; no result observed from treatment with phosphorus. (*b*) Cod-liver oil 60 g. daily to replace former additions to diet; phosphorus pills omitted. After five days' treatment: pressure pains much less; abduction test causes slight pain. Patient shows great improvement and has lost expression of suffering; can sit up in bed without using hands, but still has great difficulty in getting in and out of bed and has to flex thighs with hands; can stand alone with feet far apart, and can take a few steps with support. Fourteen days: trace of pain on compression of ribs but not elsewhere; can move from bed slowly without pain, stands without support, walks with help of stick; has shuffling gait. Discharged March 17th, 1920.

CASE 8.—Rosa T., aged 30; bookbinder; admitted May 20th, 1920. The unusual feature of this case was the occurrence of the disease in a severe form in so young a woman; symptoms had been present and progressing for more than a year, but patient had only given up work two weeks before entering hospital. On admission gait was stiff and steps were short and shuffling; all body movements, such as bending or getting into or out of bed, were difficult and painful and were only possible when aided by hands; pain was caused by pressure over frontal, malar, and nasal bones, ribs, lumbar vertebræ, sacro-iliac joints, shaft of femur, and borders of tibiæ; pain on abduction of flexed thighs very acute.

Treatment.—(*a*) Fat-free diet, with addition of green vegetables. Daily food-supply was equivalent to 2000 calories, and consisted of bread, rice, oatmeal, peas, beans, lentils, cocoa, sugar, and chocolate. In addition a large amount of green vegetables was consumed, the daily allowance being at first 400–500 g., and later 700 g. Vegetables used were spinach, lettuce, cabbage, cress, asparagus, and cucumber. For cooking purposes 5 g. of olive oil daily was allotted; this diet was continued for 18 days. Progress: After 18 days' treatment patient had gained 1 kg. in weight. Distribution and degree of pains on pressure were unaltered; gait was still stiff and body movements difficult though less so than before. Progress of case was not satisfactory and patient was disinclined to take larger amounts of green vegetables, so it was decided to discontinue treatment on these lines. (*b*) 60 g. of animal fat added to the diet daily, and no green vegetables given; cod-liver oil 30 g., butter 20 g., and one egg were given daily and 50 g. of dried full milk were substituted for the fat-free milk. Total calories 2500; protein 60 g. After 12 days' treatment: gait much more free, and body movements made with ease and without use of hands; abduction of thighs causes very slight pain, and all pressure pains have disappeared or are diminishing; increase in weight since admission of 3 kg. In general a marked improvement in patient's condition.

attention to the good effect which improved conditions of life exert upon the disorder It is the opinion of Schlesinger that more careful observation and accurate diagnosis will discover the disease to be more widely distributed than has been hitherto supposed

The causation of osteomalacia has hitherto been generally ascribed to disordered calcium metabolism, attributable to abnormal action of endocrine glands and associated with poverty and destitution This conception of its ætiology is also adopted by Edelmann and Schlesinger, who consider that hunger osteomalacia is brought about by the effect of undernourishment upon the activities of one or more of the ductless glands The fact must be emphasised, however, that the connexion between " hunger-osteomalacia " and osteomalacia that occurs in pregnancy is far from clear Despite the widespread distribution of " hunger osteomalacia " among the older section of the population of Vienna, no increased incidence of the typical osteomalacia of pregnancy was reported among child bearing women, and the conditions favourable to the occurrence of " hunger-osteomalacia " must, in general, be regarded as different from those that determine the onset of the disease in pregnancy

Specific Deficiencies in Diet as a Possible Cause of Hunger Osteomalacia

The consideration of diet as a factor of specific importance in producing osteomalacia of pregnancy does not seem to have been undertaken Fehling, however, refers to the possibility of averting the disease by improved diet In the outbreak here recorded the question of diet was of primary importance, and prophylaxis and cure were effected by diet alone

In considering external conditions in Vienna during the past five years, the most striking unusual circumstance has been the food deprivation suffered by the population There is no doubt in the minds of those who studied the outbreak of hunger osteomalacia in Vienna in 1918–19 that the condition was, indirectly at least, dietetic in origin This is made clear by the resolution introduced by Prof Dr Schiff, and adopted unanimously by the Gesellschaft der Aerzte at their session on March 14th, 1919, calling the attention of the Inter Allied Food Mission to this famine disease, and begging for quick and generous supplies of food as the best means of dealing with it

The food supplies of the city of Vienna diminished progressively from 1917 onwards, and during the winter of 1918–19, and of 1919–20, were reduced to a minimum The diets of the patients examined by us had consisted mainly of bread and vegetables, with small amounts of flour and sugar Milk, butter, and eggs were unknown, meat was not consumed, the price being prohibitive, and the only fat in the diet was a small and irregular supply of lard It was the opinion of some that the disease, although confined at that time to the poorest class in the city, was not strictly a starvation disease, but was rather the result of a qualitative deficiency in the diet caused by lack of certain definite foods The patients were always thin, but not emaciated, and while the process of cure in hospital was invariably accompanied by increase in body weight, the successful treatment of out-patients was accomplished without any such gain in weight Lack of fat was the most striking deficiency in the patients' diets prior to the development of osteomalacia

The value of certain fats in diet has been much emphasised recently by the results of experimental work upon growth in young animals

The work of Falta and Nogerrath (1905), Stepp (1911, 1912) of McCollum and his co workers (1913–1916), and of Osborne and Mendel (1913, 1915), has shown that in young rats growth may be entirely inhibited by a diet adequate in calories and in protein supply if certain fats are absent and will be restored if a small amount of these fats be again included in the diet This result was attributed by McCollum not to the fat in itself but to the presence of a certain vitamin or accessory factor dissolved in the fat, this vitamin be called the " fat soluble A factor " It is present to some extent in most fats, but those of animal origin, such as fish liver oils, beef fat, mutton fat and butter, contain it in greater concentration cod liver oil being particularly rich in this vitamin The existence of this factor in green leaves has also been established

It is to be remembered that one view of the ætiology of the analogous disease rickets is that the disease may be attributed to a lack of fat in the diet of infants (Cheadle (1906), Still (1907), Holt (1907)) In Austria cod liver oil containing an addition of phosphorus is a classic remedy for rickets and has been widely used for osteomalacia, but the view commonly held is that the beneficial result that follows is to be ascribed to the phosphorus rather than to the oil, although the investigations of Schabad (1909, 1910) upon calcium metabolism in rickets before and during treatment, have shown that the cod liver oil rather than the phosphorus is to be regarded as the active constituent in increasing the retention of calcium Schabad also investigated the effect upon calcium metabolism of sesame oil and, in conjunction with Sorochowitz, of olive oil These oils were found to influence calcium retention in a degree which was insignificant by comparison with that of cod liver oil

These results of Schabad have received interesting confirmation from the recent work of Mellanby (1918, 1919) upon experimental rickets in young dogs Rickets occurred in puppies fed upon diets poor in fat soluble vitamin—i e, containing fat in the form of olive oil or lard, but not when cod liver oil or butter was substituted for these fats Mellanby has advanced the view that rickets is a dietetic disease caused by a deficiency in the diet, not of fat per se, but of some factor contained in certain fats Three studies on experimental rickets in rats have appeared recently by McCollum, Simmons, Parsons Shipley and Park (1921) In their experiments rachitis and similar disturbances of osteogenesis were produced by deficient diets and they have demonstrated that some substance in cod liver oil causes calcium to be deposited in the same fashion in which deposition occurs in spontaneous healing of rachitis Their observations lend support to the view that an anti rachitic factor present in animal fats plays some rôle in the normal process of ossification Hess (1917, 1920, I and II), while admitting the prophylactic or curative action of cod liver oil upon rickets in children, considers that lack of the fat soluble A vitamin is only one among several factors concerned in causation of the disease

Concurrently with the outbreak of " hunger osteomalacia " in Vienna, during 1919 and 1920, there has been an unusual prevalence of rickets among infants and young children, and of late rickets among young adults This suggests that all these disorders may have a common origin, and may represent a reaction to some unusual circumstance interfering with normal metabolism and the proper nutrition of the bony tissues

The identity of rickets and real osteomalacia from the anatomical standpoint has been strongly supported by the histological work of Pommer (1885), Looser (1908, 1920), and others The different theories which have been advanced regarding the ætiology of osteomalacia and of rickets form two parallel series For each disease there are theories involving (1) disordered action of the ductless glands, (2) defective hygiene, (3) defective diet, and (4) bacterial infection (Morpurgo 1900, 1902, 1907) The occurrence of tetany with osteomalacia, and the association of this condition in childhood with rickets, form another important parallel between the two diseases With such indications of correspondence between rickets and osteomalacia, it was of the greatest interest to ascertain whether evidence in support of a similar dietetic theory for both diseases could be obtained during the outbreak of hunger osteomalacia in Vienna

Result of Dietetic Treatment upon " Hunger-Osteomalacia "

From earlier observations it was known that simple rest in bed with good diet was a successful form of treatment for the lighter cases of hunger-osteomalacia Cod liver oil containing phosphorus was highly esteemed as a curative substance, the phosphorus being regarded as the active agent When cod liver oil could no longer be obtained in Austria, different vegetable oils, with additions of phosphorus, were employed for treatment In certain cases good results were reported from the was provided by the kindness of Prof. Schiff, and shows the numbers of new cases reporting themselves each month for treatment during 1919 and 1920. The number of new *cases reporting sick may be taken as a measure of the prevalence of the disease.* Although no patient, as a rule, reported for treatment until he had been ill a month or more, yet patients would not be likely to report for treatment unless they felt themselves getting steadily worse. In each year the apex of the curve comes in the same month—April—but in 1919 fresh cases appeared in considerable numbers through May, June, July till August, when there was a sudden rapid drop. At the time when this drop occurred in 1919 Prof. Schiff reports that he attributed it to the arrival of a large consignment of American bacon in the city. In 1920, however, the great drop in the number of fresh cases came in May, and in June they had fallen to a very low figure indeed, so that this period in 1920 corresponds with August in 1919. In June, 1920, there was no special large influx of American bacon or of any other foodstuff into Vienna, and it seems probable that the much more *rapid diminution in the number of fresh cases in 1920 as* the year advanced must be attributed to the exceptionally early spring following on a winter of no severity. The early spring produced salads, green vegetables, and a little meat at a price which the poor could pay six weeks or two months earlier than would normally be the case.

The actual possible bearing of the supply of green vegetables on the ætiology of the disease is discussed elsewhere, but it is as well to make it clear that it is not believed that scurvy played any part. No symptoms of scurvy were ever seen or reported among the patients and the great predominance of white cabbage and roots, even though well cooked, in the diet producing hunger-osteomalacia, makes any incrimination of scurvy almost unthinkable.

Special Investigation of 177 Cases: Methods Employed.

Since one of the writers (E. N.) was a regular member of the Krankenkasse medical staff, it was possible to see the patients in the ordinary course of Krankenkasse business and to distribute treatment through the channels already organised. The treatment given in this investigation was therefore, in many ways, a continuation of the previous treatment and may very fairly be compared with it. It was proposed to treat roughly one-third of the cases with 200 g. weekly of cod-liver oil,‡ one-third with 100 g. weekly, and one-third with 200 g. weekly of the vegetable oil containing phosphorus, "phosphor oel," which had previously been used in Krankenkasse treatment, and to observe the result. The cod-liver oil used for treatment was obtained through the kindness of several of the relief missions, the Friends' Emergency and War-Victims' Relief Committee, the Vienna Emergency Relief Fund, and the International Spitalshilfsaktion, and was the ordinary refined cod-liver oil of commerce. The vegetable oil came from the Vienna municipality central fat control and was unfortunately of unknown origin: a sample has, however, been brought to England, and it is hoped to identify it and test its growth-promoting powers on rats. (See Appendix.)

The method adopted in dealing with the patients was to see them in turn and question them as to the duration of their illness and the mode of onset of symptoms, and any previous treatment which they might have received. The disease was often reported as of long standing (1–36 months). In cases which had been ill for more than a year, a remission was generally admitted in summer, followed by a relapse in winter. Many patients were entirely untreated, others had had treatment with phosphor oil or had been taken into hospital. A few cases treated in hospital had enjoyed remarkable improvement, but just as often this was not the case and none spoke enthusiastically of cure in the past. Almost all cases said that pains had appeared first in the feet and legs, later in the sacrum, and later still in the ribs, but this order of development was not universal.

Three special symptoms were selected as a standard of severity, the gait, the degree of difficulty manifested in trying to go upstairs, and the tenderness of the ribs to pressure; for this last symptom it was usually enough to watch the patient's face while exerting pressure on the ribs. According to the severity of each, half, one, two or three crosses were given to each symptom. It is obvious that such a method of standardisation can only give a very rough measure of the severity and progress of the disease, but in a disease which has no more marked objective symptoms than these, it is only possible to adopt some such procedure. Further it was necessary to see a large number of patients in a morning, and no more detailed examination was possible.

To each patient was given a card, with the method of treatment written on it, and he was instructed to obtain weekly a fresh bottle of oil, which would be inscribed on the card by the dispenser. He was further to present himself to the doctor again in about a fortnight. At the next visit, the number of bottles of oil consumed by the patient were noted down by the doctor, but it was never found possible to compel the patients to fetch or send for their bottles at perfectly regular intervals. At each fresh visit to the doctor the patient was put through his paces, and the gait, stair-climbing capacity, and rib pressure pains were charted again with crosses. Most patients showed some improvement after a fortnight, and very marked progress in a month; if they failed to do so, the treatment was usually changed about the fourth or fifth week to cod-liver oil if they were receiving phosphor oil, or to larger doses of cod-liver oil if they were already receiving it. When patients began to improve, the improvement was almost always first manifest in the ribs, and often the ribs were no longer sensitive to pressure at a time when the gait had as yet scarcely shown any improvement. The sacral region and gait then gradually improved, until the walk and stair-climbing appeared normal; but long after all objective symptoms had vanished, the patient still complained of pains about the thighs and feet, particularly in the insteps. In comparing the time required to effect a cure with the three different treatments, it was decided to disregard such purely subjective symptoms; there was no means of standardising them, and although there is no doubt that they were often genuine, sometimes they may not have been, and the desire to continue to obtain a weekly bottle of oil and sick-pay benefit cannot be excluded. All oil, and particularly cod-liver oil, fetched a very high price in Vienna, and a patient almost cured might well wish to sell his weekly bottle. It is not thought that there was danger of such fraud earlier in the disease, for the patients were in great pain and misery; many of them would weep, and their eagerness for the oil was in some cases almost wolfish. In view of the considerations just stated, it was decided that in studying the rate of cure, the course of the disease after disappearance of objective symptoms should be neglected; the term "cure" is therefore used in this study to indicate the time at which all objective symptoms had vanished. It is not to be supposed that treatment ceased at this point.

An attempt was made to weigh patients every time they came up for examination, but it had to be abandoned. Time did not permit of each patient being stripped, and the change from winter to summer made it impossible for them to come always in the same clothes. The patients were all thin, as is, indeed, the entire poor population, but they were not especially emaciated. Enough information was obtained to show that no very considerable increase of weight accompanied the cure; patients showed perhaps 1 kilo, 1½ or 2 kilos gain over the whole period of two or three months. Of 21 cases who were weighed at the beginning of treatment, and again one to three months later, after a marked improvement in their symptoms had taken place, an average gain of 3·5 kilos is recorded, if a difference of about 3 kilos between the winter and summer clothing is allowed for. Thus it is clear that there was no tremendous regaining of weight, corresponding with the enormous losses some of the patients claimed to have suffered; one case, for example, Juliana B., claimed to have lost 30 kilos, another, Leopoldine G., 17 kilos, and a third, Rudolf N., 20 kilos. Neither did the patients appear much fatter after the cure had set in, although their appearance was much changed; the colour was much better, and the whole mien of the people altered; from being a waiting queue of the most pitiful human wreckage, scarcely able to creep along, ready to burst into tears at a word of questioning, they became a row of brisk individuals, cheerful and extremely grateful.

Analysis of the Results.

In analysing the figures, dealing with the rate of cure in the different treatment groups, a number of factors come into play which tend to destroy the greater accuracy which it was hoped to attain by authors in a separate communication, but they have permitted their general conclusions to be stated here Cod liver oil was found to be definitely superior to rape oil containing phosphorus (0 01 per cent), and large doses of the plant oil (200 g weekly) gave a rate of improvement about equal to that obtained with smaller doses of cod-liver oil (100 to 150 g weekly)

---

‡ In the whole series of cases only one was found, Marie P., who was unable to tolerate the large amount of oil; on small quantities she made only very slow progress; on large quantities she lost appetite, her digestion became disordered, and the pains due to osteomalacia became more severe.

(*f*) *Influence of Green Vegetables* —In order to throw light on the question whether fat or the fat soluble accessory factor was to be regarded as the effective agent in treatment, it was important to ascertain whether green vegetables (another source of the fat soluble A vitamin) had any curative effect on this disease The history of relief in summer and return of symptoms in winter given repeatedly by recurrent cases suggested that this might be the case It was difficult to put the theory to a practical test, for most of the patients were old or elderly and feeble, and a diet devoid of fat and containing large amounts of cabbage, salads, and spinach would not have been tolerated Also it was impossible to arrange such a diet in the period January–April, 1920, when most of our observations were made. An attempt was made, however, in the case of a woman, aged 30, who entered hospital at the beginning of May, suffering severely from hunger osteomalacia Her diet was strictly controlled and contained as much green vegetables as could be tolerated and 5 g only of fat in the form of olive oil The patient consumed an average of 700 g of green vegetables daily, but made no appreciable progress in 18 days Her diet was then changed and the green vegetables replaced by 30 to 40 g of cod liver oil and 20 g butter daily, and improvement took place rapidly after the change The case is described in detail in the Appendix, Case 8

General Character of the Recovery.

The general character of the recovery was always the same, but occurred more rapidly in hospital patients than in those treated as out-patients and carrying on their ordinary occupations at home After a few days on effective treatment body movements became less painful and the patient could stoop or turn more readily. The gait often improved within a week, and although it retained a waddling character it was less stiff and showed a more natural movement at hips and ankles. Within the second week there was often great remission in the pressure pains, and the abduction pain was usually less. As a rule the pains caused by compression of the ribs continued longer, and the upper ribs were free from pain earlier than the lower ribs The most obstinate symptoms were always the pains on movement in the lumbo sacral region and in the tarsal bones, but these disappeared within 4–6 weeks, and did not tend to recur if suitable amounts of fat were taken regularly as a prophylactic.

The eight cases described in detail in the Appendix were selected to illustrate various types of symptoms and different methods of treatment. In many the comparative value of the respective additions to the diet is well seen from the alteration in the rate of recovery when one treatment was substituted for another.

Summary and Conclusion.

1. The occurrence of "hunger-osteomalacia" in Vienna during the period of greatest food deprivation, its incidence among the poorest inhabitants and the beneficial effect of improved diet without any other form of treatment, suggested that the disease was of dietetic origin

2. The disorder affected chiefly middle-aged and old people of both sexes The characteristic symptoms of the condition are pain on body movement, a waddling gait, difficulty in mounting stairs, severe pain in sacral region on pressure or movement, and pain in the ribs on compression of the thorax. Tetany may occur in association with the disease

3 Forty eight cases were treated by making additions to patients' diets in the form of carbohydrates, cereals, and fats of various kinds

4 Little improvement could be demonstrated after addition to the diet of sugar or cereals (i e, extra calories without fat), although in many instances the previous diet had been very scanty.

5 Recovery followed the addition of either cod-liver oil, butter, oleo-margarine containing 80 per cent of animal fat, or olive oil The beneficial influence was in the order named above, cod-liver oil being far the most effective. Some of the severer cases did not improve until cod-liver oil was given.

6 That the relative therapeutic value of the fats used corresponds roughly with their content in the fat soluble A vitamin is regarded as significant

7. It is also possible to interpret the remission of symptoms of "hunger osteomalacia" in summer and their relapse in winter as due to varying supplies of vitamin A in the diets, for, during summer, inclusion of green vegetables in the diet provides a valuable source of this vitamin. One attempt, however, to cure a severe case with a fat-free diet, rich in green vegetables, was not successful. More observations are needed on this point.

8. The increase in Vienna of rickets in children and late rickets in young adults, simultaneously with the occurrence of "hunger osteomalacia," suggests that the three disorders may be due to the same cause.

In conclusion we wish to express our thanks to those members of the medical profession in Vienna who have afforded us the opportunity of carrying out this investigation. We are specially indebted to Prof. H. Schlesinger, of the III Medizinische Abteilung of the Allgemeines Krankenhaus, who permitted us to make special study of cases in his wards, and gave us the benefit of his previous extensive experience. Our thanks are also due to Prof. K F. Wenckebach and Dozent Dr. Porges of the I. Medizinische Klinik of the University, and to Prof. Dr. Schiff of the Zentral Verband der Krankenkassen; also to those members of the nursing staff who cheerfully undertook all the extra work involved in the preparation of special diets.

For the supply and transport of special foodstuffs we have to thank the British Section of the Inter-Allied Food Mission then stationed in Vienna; and we desire also to record our thanks to the Mission of the Society of Friends working in Vienna for much help and cooperation, especially in supplying from their stores particular articles of diet essential for our investigation.

APPENDIX.

Following are the notes on eight cases.—

CASE 1 —Antonia B, aged 48, admitted March 20th, 1920 Severe recurrent case, symptoms first noted in July, 1919, improved in August and September, 1919, and reappeared in January, 1920 On admission patient had shuffling gait and complained of great pain on walking and on all movements involving the trunk muscles She had acute pain on compression of ribs and on sudden abduction of flexed thighs Pain was elicited on pressure over inner border of tibia, shaft and condyles of femur, and over iliac crests; also along shaft of each humerus, especially at insertion of deltoid muscle

Treatment —60 g of olive oil daily with carefully controlled diet of fat free milk, cereals, pulses, and fruits Calorie value of diet 2500 daily Protein content 60–65 g.; fat content 60 g. This diet was begun on third day after admission and continued unchanged for 32 days, and the patient's weight increased by 3 3 kg Progress—Gait improved within six days of admission. After nine days' treatment: distinct general improvement; gait still stiff but no longer waddling and patient can take longer steps, can get in and out of bed more easily, less pain on compression of ribs Eighteen days great progress; gait normal, can spring from bed without use of hands, no pain on abduction of thighs, pressure pain persist over lower ribs and sacrum, and over ankle-joints and tibiæ Twenty five days. pains in ankles still present, no other symptoms, discharged cured April 21th, 1920, but symptoms recurred.

CASE 2 —Anna H, aged 65, admitted Jan 15th, 1920 Symptoms stiff waddling painful movements on walking, acute pain on compression of ribs and abduction of thighs; some pain on pressure over pubic symphysis and rami

Treatment —(*a*) Diet enriched by abundant extra cereals and carbohydrates without addition of fat on eighth day after admission After 15 days' treatment, all symptoms unchanged (*b*) 50 g margarine (containing 80 per cent. of animal fats) and 15 g olive oil added to daily diet After 10 days' treatment gait much improved; pressure pains in ribs persisting Seventeen days: normal gait; slight pain on compression of ribs; no other symptoms, patient discharged Feb 26th, 1920.

CASE 3 —Mater P., aged 57. Treatment begun Jan 10th, 1920, in convent Symptoms present for past two years, with remissions during summer months Severe case, and walks only with great difficulty. Marked pressure pain over each treatment group a certain number of cures were unfinished—that is to say, that although good progress was being made, all objective symptoms had not disappeared on the last occasion on which the patient was seen. These unfinished cures are represented in the table because they cannot fairly be entirely neglected, but they are left out of consideration because they are inconclusive. The table shows that in the five treatment groups represented the dates of "cure" ("cure" being used in the special sense already described p. 5) distribute themselves pretty equally from the second to the tenth week, with a few as late as the fourteenth week. There is certainly no great superiority in rate of cure in any one group over any other group. Such a table suggests that as soon as sufficient of the curative substance is supplied rate of cure is not appreciably hastened by more intensive treatment; probably the maximum rate of repair has been attained, but it is also possible that repair at an even more rapid rate may be only prevented by an insufficient supply of something else, the lack of which acts as a limiting factor.

The Possible Value of Phosphorus.

The work of Schabad (1909, 1910) on calcium retention in the cure of rickets by treatment with oils suggests that an insufficient supply of phosphorus may have been such a limiting factor. He found that cod-liver oil had great power in increasing calcium retention in rickets and that this power is further heightened on addition of phosphorus to the cod-liver oil. If, then, there is a parallel between hunger-osteomalacia and rickets, it is possible that addition of phosphorus to cod-liver oil might also hasten the cure of osteomalacia. It is unfortunate that in our experiments the vegetable oil had an addition of phosphorus while the cod-liver oil had not; had the cod-liver oil also contained phosphorus it is possible that its superiority over the vegetable oil might have been even more marked. Schabad also found that certain vegetable oils had power to increase calcium retention in rickets, but in the case of sesamum oil this was not so, and addition of phosphorus to the inactive oil failed to awake any activity in it. His work, therefore, makes it clear that the coöperation of another factor in the oil is required and that the absence of such a factor may entirely limit any curative power of the phosphorus.

From the present experiments it would therefore seem that in the treatment of hunger-osteomalacia a dose of about 100 g. weekly of cod-liver oil is the most economical form of therapy to commence with in all cases, increasing the amount later only in those refractory cases which make little or no progress upon this dose. From the present experiments no conclusion can be drawn as to the possible coöperative value of phosphorus. Reference to one particular case is made in more detail; it is a particularly striking one but is also characteristic of a large number in which the result of treatment with cod-liver oil stands out in contrast with that of the former routine Krankenkasse treatment with phosphor oil.

The patient, Wilhelmine O., gave a history of having been ill for 30 months; for nine months, March, 1919, to January, 1920, she had been receiving the routine Krankenkasse treatment with phosphor oil, which left her condition unchanged. When first seen at the beginning of March, 1920, she was unable to dress or undress herself, and could not even turn her head without pain. She showed a rapid improvement on cod-liver oil, 125 g. weekly, and by the first week in June—i.e., after three months of treatment—described herself as "Vollständig gut," save for a slight pain in the lumbar region. Thus all objective symptoms and almost all subjective ones also, of an illness lasting 30 months, were dissipated in three months by rather more than one tablespoonful of cod-liver oil daily. This patient had been known to one of the writers (E. N.) for the whole 12 months during which she had attended at the Krankenkasse, and the unaltered condition during the nine months of phosphor oil treatment, followed by the cure on three months cod-liver oil, was most impressive.

When patients were considered to be cured the treatment was discontinued, and as far as it was possible to judge in the time, relapse did not tend to take place. Treatment was in no case stopped till May or June and the experiment was terminated at end of June. Patients when sent away were instructed to come back at once if they felt worse, and of over 70 patients so discharged only three or four had returned announcing a relapse; in these cases the relapse only consisted in a reported return of subjective symptoms which may or may not have been truly stated. It seemed most probable that the patients would remain in health through the summer but would relapse again towards the end of the year unless treatment were resumed or the food obtainable in the winter became better.

Effect of Treatment on Cases of Rachitis Tarda.

Of the 10 cases of rachitis tarda encountered, 4 cases (2 boys and 2 girls) were chosen out for in-patient treatment and will be described in a later communication. The other 6 were all boys, one 16, one 17, one 18, two 19, and one 20 years of age. Three dosed with 200 g. of cod-liver oil weekly, and one dosed with 100 g., made excellent steady though slow progress; two dosed with 200 g. weekly of phosphor oil, but very irregularly taken, made little or no progress.

Bearing of the Results on the Ætiology of the Disease.

As far as the present mass experiment throws light on the ætiology of hunger-osteomalacia, it seems to support the hypothesis that the disease is due to a deficiency of the fat-soluble accessory factor. The disease was cured, and dramatically cured, by an addition of fat only to the diet. It is true that the plant oil contained phosphorus, but the cod-liver oil had no such addition, though it may itself have contained phosphorus to some extent. It has already been suggested that the absence of phosphorus in the cod-liver oil may have acted to some extent as a limiting factor, but there is no evidence that the rate of cure bore any relation to the amount of phosphorus administered. There is evidence, on the other hand, that the cod-liver oil cured in quantities in which the plant oil did not, and that bad or obstinate cases yielded to cod-liver oil when they would not do so to plant oil. This evidence seems good enough to exclude fat as fat and to point to some other property, possessed in greater measure by cod-liver oil, as the curative agent. One such property cod-liver oil is known to possess in its rich content of the fat-soluble A accessory factor.

The difference between the winter and summer diet of the population and the corresponding seasonal alteration in the severity and prevalence of the disease yields another interesting piece of evidence, connecting the disease with a deficiency of the fat-soluble A factor. The winter diet of the poorest of the Vienna population is chiefly bread, "Kraut," and root vegetables, while the summer diet is principally enriched by the addition of green vegetables and salads. The kraut used in winter is the white hearts of cabbages, which are stripped of their green leaves in the autumn and are then stored in the same way as root vegetables. Unpublished experiments at the Lister Institute, on guinea-pigs, have shown that while green cabbage is growth-promoting even in small amounts, white cabbage in much larger amounts is not so; for instance, 5 g. of raw green cabbage, when added to a diet deficient in the fat-soluble A factor produces good, though not fully normal, growth in guinea-pigs, while 15 g. of white cabbage added to the same diet produces no growth at all. A similar observation for other etiolated shoots has been made by Drummond and Coward (verbal communication), using young rats. The white leaves are, however, not deficient in the anti-scorbutic factor (Delf, unpublished experiments). The bread and root vegetables which make up the remainder of the diet of the poor have been shown again and again, with the exception of carrots, by McCollum and his co-workers to be deficient in the fat-soluble accessory factor.

More evidence is needed in order to clear up completely the question of the ætiology of this disease, and it is possible that in the deplorable event of the

II —COMPARATIVE TREATMENT OF CASES OF HUNGER OSTEOMALACIA IN VIENNA, 1920, AS OUT PATIENTS WITH COD LIVER OIL AND PLANT OIL

By E MARGARET HUME,
LISTER INSTITUTE
AND
EDMUND NIRENSTEIN, M D,
VIENNA

Report to the Accessory Food Factors Committee appointed jointly by the Lister Institute and the Medical Research Council

AN *investigation on 177 out patient cases of hunger*-osteomalacia was made at the central office of the Verband der Krankenkassen Wiens und Niederosterreichs, VI Konigseggasse 10, Vienna The chief medical officer, Prof A Schiff, very kindly offered every possible facility for the research The investigation took place between February and June, 1920 The central office of the Verband der Krankenkassen is the chief office of a large sick benefit organisation which has a number of branch offices distributed throughout Vienna The subscribers, when ill, notify the fact to their local branch office and are usually treated there, but in the case of hunger osteomalacia the method was adopted of sending all patients to be treated at the head office Presumably this line was taken because the disease was previously unknown and the best method of treatment was not established

During the year 1919, when the disease was first recognised, 924 new cases presented themselves for treatment between March and December In the first six months of 1920, 620 new cases came up for treatment, and in addition many old cases were *attending regularly From this mass of material* about 200 suitable patients, in whose case the diagnosis was clear and unobscured, were selected for special study in the month of February

Previous Treatment and Special Features of the Krankenkasse Cases

The previous treatment at the Krankenkasse had consisted in dosing the patients with a plant oil containing phosphorus (0 01 g P per 100 g oil), a treatment based on the belief that phosphorus has a curative value * Bottles containing 100–150 c cm of the oil were dealt out and patients were supposed to come up weekly for a new bottle, but in practice, living as they did at great distances from the central Krankenkasse, and being severely handicapped in moving about by their painful disease, they did not come so often All that can be said as to the dose taken, therefore, is that it was never more than about 20 g of the oil a day and seldom as much Many patients stated that they had felt no improvement while taking the oil and many were certainly in a deplorable condition when first seen, although they had had treatment for many months

Before dealing with the special study there are some points of general interest in connexion with this large group of cases which deserve mention

Age and Sex of Patients —The patients were of both sexes with some preponderance of the female sex, out of 177 cases 44 per cent were male and 56 per cent female It is possible that the female sex is actually more liable to the disease, but it is probable, on the other hand, that the preponderance was due to economic causes—namely, to the greater poverty and consequently worse food of old and single women dependent on their own earnings, for such the cases chiefly were The patients were all very poor, *the largest numbers of cases came from the 10th, 12th, and* 16th Bezirks, which are the poorest districts in the city Many of the cases were very old, and although it is probable that old age does increase the liability to the disease, here also the economic factor cannot be neglected Of 131 cases whose ages were noted all except 16 were over 40, and more than one-third were between 60 and 70 (see Fig 1) On the other hand, some persons of all ages from 19 to 77 were seen who were suffering from the disease At the younger age limit, under *25*, the disease merges into the syndrome of rachitis tarda, of which 10 cases were seen among the 177 selected patients, one or two cases were seen which appeared to be transition cases, and showed the symptoms characteristic of osteomalacia and rachitis tarda *at the same time* † *Many patients were too old to be in* work, and the rest were drawn from a number of different trades, but by far the larger number were unskilled workers

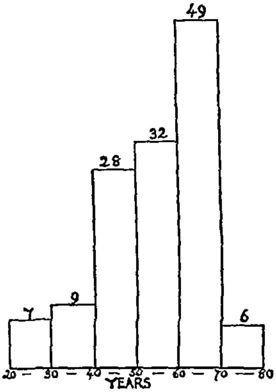

FIG 1 —Distribution of ages among 131 cases of hunger osteomalacia.

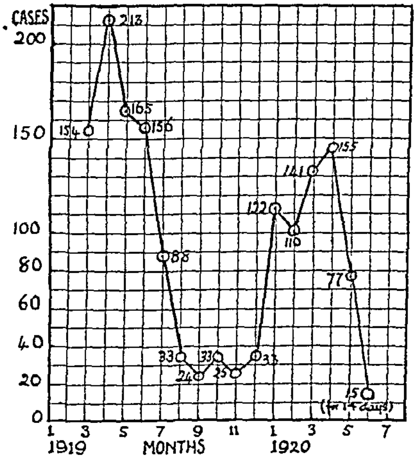

FIG 2 —Monthly record of new cases reporting sick with hunger-osteomalacia at the Krankenkasse, March, 1919–June 1920

Diet —The diet, particularly in the winter, *had consisted* principally of bread and kraut, the white heart of the autumn cabbage as opposed to the green kohl, together with root vegetables Hunger osteomalacia shows a marked seasonal incidence in winter and spring, corresponding with, it is believed, the season of worse diet The curve (Fig 2)

Statistics.

As said above, the last epidemic started in Siberia, but later on, when the cases at Manchouli were many, especially among the Russians, certain towns in Siberia were reinfected by escaping refugees. In Manchuria proper the following table shows the places infected from west to east, together with the first cases reported, and total number of deaths.

Places Infected with Plague from West to East.

Town.	First cases recorded.	Total deaths.
Manchouli	Sept. 7	1141 (R. 334 : Jan. 1)
Dalainor	Jan. 13	1017 (R. 4)
Hailar	Oct. 22	98 (R. 27)
Mentuho	Jan. 30	4
Buketu	Feb. 3	25
Ananchi	Feb. 3	84
Tsitsikar Station	Jan. 27	88
Tsitsikar City	Jan. 18	1734
Fulardi	Feb. 10	48 (R. 3)
Anta	Mar. 19	25
Tuichingsan	Mar. 5	28
Harbin District	Jan. 22	3125 (R. 8 : Jan. 3)
Hulan	Feb. 7	322
Ashoho	Feb. 12	123
Imiampo	Mar. 15	35 (R. 1)
Hantaoho Tzu	Mar. 27	16
Hailin	Mar. 8	7
Shihtaoho Tzu	Mar. 25	19
Suifenho	Mar. 14	12 (R. 2)
Shwangchengpu	Mar. 14	134
Yaomen	Feb. 3	21 (R. 1)
Changchun District	Jan. 31	77
Yu Shu	Mar. 8	153
Mukden	Mar. 29	4
Koupangtzu District	Mar. 27	18
Other cities	—	150
Total for Manchuria		8508

These figures include 380 Russians and 4 Japanese. Other places infected besides Manchuria were:—

Vladivostock and Ussuri	April 9	520 (R. 40)
Sangyuan dist. (Chihli Province)	Feb. 24	200
Chefoo and Shantung	May 3*	80
Total		800

* By steamer.

Seven infected rats were discovered at Vladivostock as well as human bubonic cases.

We made and distributed 60,000 anti-plague gauze masks and 8000 doses of anti-plague vaccine from our laboratory. In addition to our routine work, our staff took advantage of the occurrence of this rare epidemic to perform a series of important bacteriological investigations.

The following are some of the findings obtained as a result of investigations made during the epidemic.

1. *How did the pneumonic plague originate?*—It may be remembered that early in September, 1920, some cases of bubonic plague were reported at Abagatui and other Siberian towns close to the Manchurian border. One patient reached Manchouli Hospital and was cured. In October a few more cases were reported from Hailar. I reached that city on the last day of October and saw the gradual merging of the bubonic into the septicæmic and later into the pneumonic form. As it was difficult to catch fleas in dark dirty rooms through dull paper-covered windows, we utilised guinea-pigs by allowing them to roam about the rooms, hoping that the fleas would attack them and thus get caught. But in this we were unsuccessful. Fly-papers were also used with no avail. Once the plague became pneumonic its spread was rapid, as being a direct infection from man to man, it followed the lines of human travel. Even the cancellation of passenger traffic on the railways only limited the number of infections, not the extent.

2. *Wherein does the real danger of the plague lie?*—This danger lies, in my opinion, in the neighbourhood of a patient in whom cough and the accompanying bacilli are already present. Infection is carried in droplet form—that is, when the moist sputum is thrown out during talking or spitting. Experiments performed in Mukden ten years ago and repeated this time at Harbin show that, under ordinary circumstances, these droplets seldom travel more than three feet. In crowded inns, with closed windows and no ventilation, infection naturally spreads rapidly, particularly at night-time when the coolies are huddled together. If a way can be found to allow persons to sleep as well as work out in the open air, however cold, infection will not take place and pneumonic plague will lose its dreadful character.

3. *Is the cotton and gauze mask efficacious against plague?*—If properly worn it is certainly efficacious. No antiseptics or strong-smelling chemicals are necessary. Masks act as filters, and the plague germ cannot pass though dry cotton-wool. When our Dr. Yuan Teh Mao died on Feb. 20th we were afraid that if the mask became moist as a result of continued breathing the germs might get attached to the wool and inhaled. We experimented with several masks from doctors and attendants which had been worn for half to four hours at a time. Cultivations were taken from the outer, middle, and inner layers of the cotton-wool. Out of 15 cultivations so made, only one—the outer covering of a mask worn for three hours—showed the plague bacilli. Nevertheless, we considered it best for those in immediate contact with patients to wear, in addition to the mask, a head-covering made of cloth with an extra piece of silk in front of the nose and mouth.

4. *Is the air of the sick room infectious?*—To prove this we allowed a series of guinea-pigs and rabbits kept in tin buckets to stay in the rooms occupied by the sick and the dead for periods varying from half an hour to three days. Up to date seven such experiments have been performed, including one at Dalainor, and 52 animals have been used. Only four animals died, and these mostly young ones, thus showing that the air of sick rooms by itself is not so dangerous as might have been expected.

5. *Why did so many burial coolies die in this and the previous epidemic?*—Usually these men were not in contact with sick persons. We suspected from the number of corpses, from whom the clothes had been removed, that perhaps these clothes might be a factor in the dissemination of the disease. We therefore cut out pieces of the clothes from in front and behind and made the necessary cultivations. Out of 22 pieces thus examined 16 were found to be infectious, thus proving that the clothes from plague victims were highly dangerous and should be burnt with the dead bodies.

6. *What action does the best known antiseptics have on plague sputum?*—We used carbolic acid, lysol, sublimate, permanganate of potash, hydrogen peroxide, alcohol, methylated spirit, and cresol, and similar milky disinfectants. Over 400 experiments were performed in this connexion. Dealers in these commodities will be surprised to learn that plague sputum is extremely resistant to their action, and more concentrated solutions for longer periods than usually recommended are necessary to destroy the bacilli.

7. *What is the best way of disinfecting plague houses?*—Our routine method of disinfection during this epidemic has been to fumigate the houses with moist sulphur gas by burning the crude sulphur in an earthen pot after the walls and floor have been sprayed with water. The floor containing the sputum is covered with slaked lime. Our doctors' clothes and overalls are fumigated with formalin gas made from 100 g. of permanganate of potash, 100 g. of hot water, and 200 g. of formalin warmed in a pot.

Fuller details of the epidemic will be furnished at the opening of the Rockefeller College, Peking, and at the Conference of Japanese Doctors at Port Arthur, while a full scientific report will appear next spring.

DONATIONS AND BEQUESTS.—The board of management of the Royal Infirmary, Manchester, have received legacies of £3000 from the late Dr. Lloyd Roberts, also £500 for a lectureship; £1000 from the late Mr. W. Sutcliffe; also £550 from the Queen Alexandra Flower Carnival, and £315 from other sources. Henshaw's Blind Asylum, Manchester, has received £1000 under the will of the late Mr. James Booth, of Didsbury; £200 from the late Mr. Joseph Core; also completion of transfer of £5340 war stock from the executors of the late Mr. Jesse Howarth. St. Mary's Hospital, Manchester, has received from the executors of the late Dr. Lloyd Roberts £5000 and £500 for a "Lloyd Roberts Lecture." £1000 from the late Margaret Ambler, £1000 from the late Mr. W. Sutcliffe, and £177 from the Queen Alexandra Flower Carnival.—The Maharajah Holkar of Indore has sent a donation of £500 to the Mental After-Care Association, Church House, Westminster, towards the expenses of dealing with patients who have suffered from nervous or mental trouble caused directly by war service.—The late Charlotte Susan Chalmers, of Aberdeen, left the following legacies: Morningfield Hospital for Incurables, Aberdeen, and Aberdeen Royal Infirmary, each £250; Royal Aberdeen Hospital for Sick Children, £100; Royal Hospital for Incurables, Putney, £10.

investigating a large number of cases In the first place, a certain number of cases have to be rejected altogether, owing to complications with other diseases, irregularity of attendance and similar factors Among those left, 130 in number, the effect of the interfering factors is to break up the three large groups planned for into a much larger number of smaller groups, groups so small that in many cases they cannot contain sufficient numbers to be representative

One such factor is the initial severity of the cases, obviously in comparing the length of time necessary for all objective symptoms to vanish, very severe cases and very slight ones could not be taken as comparable Cases were therefore broken up into four degrees of severity, according to the number of crosses given to the three objective symptoms, as already described, here was wide scope for human error On working out from the patients' cards the average weekly dose of oil taken, it was found that the oil had been drawn so irregularly that patients fell into six groups, instead of the three planned—i e , over 150, from 100 to 150, and under 100 g weekly of cod liver oil, and the same of phosphor oil Since each treatment group contained four different degrees of severity of the cases, 24 groups were revealed instead of the three sanguinely hoped for When 130 patients have to be divided among 24 groups instead of three the result loses very much of the reliability that was hoped for from the use of large numbers

Further possible sources of error were alterations in the patients diet, either through the change of the season or through free gifts from relief organisations The latter certainly took place to some extent, but was spasmodic, and did not appear sufficiently important to merit attention The seasonal alteration in diet might have been a serious source of error, since the investigation was carried on from the end of February to the end of June About mid April patients began to report eating spinach twice a week, and by the end of May occasional eggs and a little meat were not infrequent It is not, however, thought that this factor is an important one in influencing the cures in the present experiment although it has been suggested as an important factor in determining the number of new cases reporting sick Patients seldom report sick with osteomalacia until they have had it for several months and are getting steadily worse, to be no longer getting worse though scarcely perceptibly better, would be enough to deter patients from reporting who had not reported already, The cures with cod liver oil and large amounts of phosphor oil were, on the other hand, so comparatively rapid that the small added improvement which might be brought about by the consumption of spinach twice a week would be unimportant Also in many cases cures were well on foot, and great progress had been made before any seasonal alteration in the available food could be detected It is therefore believed that this factor can be neglected in the analysis of the figures

The results show clearly that hunger osteomalacia can be cured by administration of cod liver oil, even in amounts of only 100 g weekly, or of phosphor oil in larger quantities, about 200 g weekly Clearly the amounts of oil previously administered from the Krankenkasse had not been large enough nor regular enough, though they were probably as large as the smaller amounts of cod liver oil administered in the experiment All patients with one possible exception, a very old and refractory case, Max L , improved when treated with 200 g of cod liver oil weekly All patients treated with phosphor oil did not improve in the same way, particularly those who by infrequent visits reduced their weekly average to less than 150 g When patients after several weeks of treatment showed no or very little improvement, or actually got worse, as was occasionally the case with phosphor oil, the treatment was usually changed from phosphor oil to cod liver oil or from smaller to larger amounts of cod liver oil In every case save one (Max L , phosphor oil 200 changed to cod liver oil 200), where such a change was made, much better progress took place after the change

Table I has been constructed to show (1) the number and percentage of patients who improved on the various treatments , (2) the number who showed no improvement , (3) the number who had changed treatment, as just described and (4) the result of the changed treatment In analysing the figures in this way, where some degree of improvement is the criterion taken cases of all degrees of severity are dealt with together, for although the severity influences the length of time needed to accomplish a cure yet it does not appear to influence the length of time in which a material degree of improvement sets in In Table I the figures dealing with 130 patients are thus analysed, and it is seen that (A) In Group I , containing two patients who received less than 100 g phosphor oil weekly, neither (i e , 0 per cent) showed improvement, while in Group IV 34 received the same amount of cod liver oil, and 31 (i e 91 per cent) showed good improvement , (B) in Group II 10 received 100–150 g of phosphor oil weekly, and 6 (i e , 60 per cent) showed progress, while in Group V, 34 received the same amount of cod liver oil, and 32 (i e , 94 per cent) showed good progress , (C) in Group III 29 patients received 150–200 g of phosphor oil weekly, and 21 (i e , 72 per cent) showed good progress, while in Group VI 21 patients received 150–200 g weekly of cod liver oil, and 21 (i e , 100 per cent) showed progress The patients whose treatments were changed are not represented again in the groups for their second course of treatment For instance, the one patient, Max L , who made no progress after being changed from 200 g weekly of phosphor oil to 200 g weekly of cod liver oil, is mentioned only in the first named group and not again in the second The figures show that even 150–200 g weekly of phosphor oil gives a percentage progress rate (72 per cent) which falls below the rate (91 per cent) for quantities of only 50–100 g weekly of cod liver oil pretty clearly indicating that the healing effect must be due to something other than mere fat as fat or phosphorus The percentage progress rates for the three cod liver oil groups lie very close together—i e , 91 per cent , 94 per cent , and 100 per cent —showing that in most cases even 50–100 g weekly of cod liver oil is sufficient for cure

TABLE I —*Comparative Progress of Patients with Hunger Osteomalacia Treated with Phosphor (Plant) Oil and Cod Liver Oil*

(A) Number of patients showing progress

(B) Number of patients showing no progress Treatment unchanged

(C) Number of patients worse or showing no or very little progress Treatment changed

(D) Number of patients showing greater progress after change

(E) Number of patients showing no progress after change

Group	Treatment	Oil g weekly	Total patients	(A)		(B)	(C)	(D)	(E)
				Total	%				
I	Phosphor oil	60–100	2	0	0	1	1	1	0
II	,	100 150	10	6	60	2	2	2	0
III	,,	150–200	29	21	72	1	7	6	1
IV	Cod liver oil	50–100	34	31	91	0	3	3	0
V	,	100–150	34	32	94	0	2	2	0
VI	,	150 200	21	21	100	0	0	–	–

An attempt has been made in Table II to compare the rate of cure on different treatments of patients whose treatment remained the same throughout For this the patients needed to be as comparable as possible, and the group of patients of moderate severity (+) has therefore been chosen, because it contains the largest numbers In

TABLE II —*Comparative Rates of Cure of Cases of Moderate Severity (+), whose Treatment Remained Unchanged Throughout*

Treatment	Total No of patients			No of weeks in which cure was completed (A) or after which treatment ceased though cure still incomplete (B)												
				2	3	4	5	6	7	8	9	10	11	12	13	14

the excreta were disposed of immediately after defæcation in an incinerator placed in or near the latrine. The danger of fly infection and the labour required for removal of the necessary buckets and their cleansing were disadvantages of the first method. A point in its favour was that "fæcal urine" was not so excessive as to prevent the whole bucket contents being disposed of in incinerators of good construction, provided these were kept supplied with sufficient fuel. In dealing with the second method, he gave details of an experiment made by the Germans at Potsdam in 1902, where the latrine seats were placed over hoppers which led direct on to iron plates and pans inside a furnace, the furnace being only lighted twice a week. The abandonment of this system was attributed to the smell, but a trial with only a bi-weekly incineration could not be considered a fair one. The McCall system, started by the Americans during the Cuban war, had been abandoned owing to expense of iron plates and fuel. Sir W. Macpherson said he had had personal experience of the method of direct incineration before the war, both in India, and Aldershot, and here the simple device of placing a layer of bhoosa or other dry material on the ground, making the men defæcate on this and then set fire to it, proved extraordinarily satisfactory. More recently, in 1915, in France and also later in Salonika, he had started a method of immediate incineration, described in the *R.A.M.C. Journal* in 1915. The essential principles were, firstly, the disposal of the urine by the men themselves, either by emptying the receptacle into absorption pits, or by passing urine into a channel leading to the pit. Secondly, the deposition of excreta into the incinerator immediately after the act of defæcation, also by the men themselves. The incinerator could be of the open or closed variety, and was frequently made out of a cresol drum, placed in or quite near the latrine. This method proved entirely successful; there was an abundance of paper on to which the men could defæcate, and the fire in the incinerator when once started by some wood or hot ashes from the cook-house was kept at a red heat by the paper and fæcal matter deposited therein. A sergeant-major of a medical unit which adopted this system in France from 1915 to the end of the war maintained that it had the following advantages: (*a*) Cleanliness, freedom from flies, and comparatively little odour; (*b*) definite area only involved and practically no soiling of the ground; (*c*) only one sanitary attendant required; (*d*) it could be placed at a convenient distance from the men's living quarters without fear of offence; (*e*) it could be constructed with materials usually available in any camp by any intelligent N.C.O. within three or four days of arrival at the permanent camping site. In conclusion Sir W. Macpherson referred to the disposal of urine by means of absorption pits. The system was in use in India before the war, and was suitable for practically any form of soil, and he gave an instance of a field ambulance in Salonika where such a pit had been made in rock so dense that "blasting" had to be resorted to for its construction, and even this had worked satisfactorily. He therefore considered that the disposal of urine was a simple matter, and there was no difficulty in arranging, where necessary, latrine receptacles by which urine was separated from the fæcal matter so as to allow of immediate incineration being carried out.

Discussion and Reply.

Lieut.-General Sir JOHN GOODWIN said that any method of disposal should be as, far as possible, fool-proof. The method of immediate incineration was ideal, and should be taught and tried in Church Lads Brigade and other camps. The difficulties in future wars would be overcome if the civilian population were instructed in its use in peace-time.—Surg. Rear-Admiral Sir PERCY BASSETT-SMITH also considered the system advocated excellent, his only doubt being whether the disposal of the urine was entirely free from risk.—Lieut.-Colonel TILBURY BROWN gave his experiences in West Africa, where the natives would incinerate their own excreta but not that of anyone else. He thought the suggested method most valuable.—Lieut.-Colonel W. BUTLER considered incineration the most sanitary and satisfactory method, and emphasised the danger of fly breeding in deep latrines. His only objections to incineration were (1) loss of manurial value, (2) occasional incomplete combustion.—Lieut.-Colonel JOHN ROBERTSON said that he approved of the dry-earth system best where water-carriage was not available, but if the system described could be adopted in territorial or civilian camps it might prove satisfactory. He suggested that wet weather might hinder incineration, and that the smell might be a nuisance.—Lieut.-Colonel E. P. SEWELL regretted that the system of immediate incineration was not known in Palestine during the war. He instanced the equipment of latrine buckets and portable incinerator carried by camel during the Palestine campaign. Frequently the equipment had to be left on the wayside for lack of transport. Lines were soon fouled by trenches, but properly constructed cesspits were sometimes of value.—Group Captain DAVID MUNRO spoke of his experiences at Basra, where the method suggested might have succeeded admirably. Deep pits outside Basra City had been of use in disposing of latrine contents.—Surg. Commander R. J. MACKEOWN spoke of the difficulty of instructing the men. He asked what method the Japanese adopted in their war in Manchuria.—Lieut.-Colonel H. R. KENWOOD thought that water-carriage was always the best and cheapest method in the long run. The dry-earth system he considered next best; it caused no odour and no flies. Incineration was valuable and useful, but he knew that in some instances this method had had to be abandoned on account of the smell; probably the system of individual incineration would cause little or no nuisance in this respect. The disposal of urine was a difficulty, and a soakaway was not always suitable.

Sir W. MACPHERSON, in reply, said that he considered the method of immediate incineration to be fool-proof; in the emptying of urine receptacles into the absorption pit the men ran no more risk than any housemaid. As to the loss of manurial value, the ash from the incinerators was of considerable use as a fertiliser. Rain had no effect on the incinerator, but, of course, the latter could be covered if desired. There was little smell in the individual method, and two small cresol drums made into incinerators had in a C.C.S. in France dealt daily with the excreta from 2000 men. There was no difficulty in instructing the men; written instructions were posted up in the latrines. In Manchuria the Japanese used deep trench latrines. He agreed that the dry earth method was good, but it was inapplicable "in the field"; obviously no single method would be suitable for general adoption.

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

THE first meeting of the session was held on Oct. 7th, when Dr. G. B. FLEMING read a paper on

The Post-natal Treatment of Congenital Syphilis.

After briefly outlining the methods and results of treatment by mercury and arsenic in various forms, he explained the methods adopted at the Royal Hospital for Sick Children, Glasgow, for injecting the salvarsan substances. The criterion of cure adopted was a negative W.R. which remained negative. Seventy-four cases treated between 1917 and 1920 had been analysed and 35 cases had been followed up for longer or shorter times after treatment. Of 47 children under 1 year, 44 had negative W.R. at the end of treatment and 15 out of 21 were still negative after six months. Of 27 children over a year old, 20 were negative at the end of treatment and eight out of 14 tested were still negative after six months same conditions prevailing in Vienna during another winter such evidence may be obtained. The ætiology of hunger-osteomalacia has not only the interest that it is the ætiology of a new disease, but it has also great importance from its relation to rickets through rachitis tarda and from the light which a knowledge of its ætiology may throw upon the ætiology of rickets. Whether it is the same disease as the already well-known osteomalacia of pregnancy appears very uncertain. Among the Krankenkasse cases only one, Marie L., was encountered that had any claim to be *diagnosed as osteomalacia of pregnancy.* This case was that of a woman beyond the child-bearing age, who, however, gave a history of osteomalacia during pregnancy going back to 14 years before; several of her children had suffered from severe rickets. If pregnancy-osteomalacia and hunger-osteomalacia are the same disease it is hard to understand why the former has not greatly increased in Vienna, but it has not done so. It cannot be that such cases were wholly overlooked; it may be that economic conditions do not on the whole press so severely on young women of the child-bearing age, who would in most cases have a husband to support them, but unless some such factor is operative it can scarcely be that hunger- and pregnancy-osteomalacia have the same ætiology.

Summary.

1. 177 cases of hunger-osteomalacia were treated as out-patients in Vienna. Of these, only 130 *entered into the final analysis of the experiment.*

2. About one-third of the number was treated with a plant oil (subsequently identified as belonging to the rape oil group) containing phosphorus, the other two-thirds with cod-liver oil.

3. Most of the patients made progress, but some of the patients on plant oil had to be transferred to *cod-liver oil, and some of those on cod-liver oil had to* have the dose increased before good progress could be made.

4. The results fall into a series; doses of about 100 c.cm., 150 c.cm., and 200 c.cm. of each of the two kinds of oil were given. The smallest doses of plant oil gave the worst result and the largest doses of cod-liver oil the best; the smallest dose of cod-liver oil was better than the largest dose of plant oil.

5. Once a good improvement was set on foot it could not be detected that the rate of progress on the different doses varied much.

6. It is provisionally concluded that cure of the disease was due to addition of vitamin A rather than of fat as fat to the diet.

7. The relation of hunger-osteomalacia to the osteomalacia of pregnancy is regarded as quite uncertain.

The expenses of this research were defrayed by the Medical Research Council.

Appendix.

A sample of the phosphor oil used in the above test was submitted to Dr. J. C. Drummond at University College, London, who reported that he had little hesitation in placing it in the rape oil group; in fact, he adds: "It is probably true rape oil itself. It appears to be fairly crude, since there is a considerable deposit of recognisable plant debris." The oil was also tested by Dr. Drummond on rats for its value in vitamin A. It appeared to be almost, if not wholly, incapable of restoring growth in rats which had declined on a diet deficient in vitamin A, in the quantities of it able to be consumed by rats; such quantities are, however, necessarily small. The authors are much indebted to Dr. Drummond for *undertaking this examination for them.*

PRACTICAL POINTS IN THE TREATMENT OF PLAGUE.[1]

BY DR. WU LIEN TEH (G. L. TUCK),
DIRECTOR AND CHIEF MEDICAL OFFICER, PLAGUE PREVENTION SERVICE.

THE beginning of pneumonic plague of 1920–21 was quite insidious. As in the outbreak of ten years ago, it began in the Transbaikal district of Siberia towards the end of summer, when a Russian *family, consisting of one woman, her son, and two* daughters, were reported to have been attacked by the disease in its bubonic form. With the exception of the man, treated at Manchouli Hospital, all died. Then two Cossack soldiers living in the same compound took the infection and died, the last on Sept. 20th. After this no more was heard until October, when the wife of a Russian guardsman, in charge of the railway bridge at Hailar, died of bubonic plague. She infected three out of five sons, who all died; also her husband, who recovered. These cases were seen by me at the Railway Hospital and were purely bubonic. Three Chinese soldiers living in the same compound also died of the disease. Owing to the free intercourse between the sick and some outside workmen, the infection was distributed in the city, and our efforts at segregation *met with only partial success. During our stay at* Hailar we could trace the gradual evolution of the plague from bubonic, through the septicæmic into the pneumonic form, after which it became most infectious and dangerous. One day the local chief of police *was attacked by the soldiers, and nine men under* observation were set free by the soldiers. Some later deaths at Hailar were traced to those who escaped, but two reached the coal-mines of Dalainor (100 miles away) and spread the infection broadcast among the coolies living in the semi-underground huts of that place. Manchouli was reinfected from Dalainor, and in its turn sent infected persons by rail to Tsitsikar, and later on to Harbin. In this way the whole line, from Manchouli to Vladivostock (1072 miles) and from Harbin to Changchun (150 miles), received the infection in a greater or less degree. Fortunately, however, owing to the early preparations made by the Manchurian Plague Prevention Service and to the splendid coöperation displayed by the authorities of the Chinese Eastern, South Manchurian and Chinese Government Railways, *as well as by most classes of people from Governor-*General Chang Tso Lin downwards, the epidemic did not reach the colossal dimensions of that of 1910–11. Possible cases were rigidly controlled, and the passenger traffic between Manchouli and *Harbin was stopped from Feb. 1st. Third-class* traffic from Harbin to Changchun was limited to only 150 persons, who, after inspection at Harbin, had to undergo quarantine for a further period of five days at Changchun. In this way, although the number of deaths at Harbin was considerable, comparatively few cases occurred south of this city. For instance, the whole of Changchun district only claimed 77 deaths from plague, and Mukden only 4 deaths, as compared with 5000 deaths in each city during the epidemic of ten years ago. The population of Manchuria had increased from 12 millions to 22 millions, while that of Harbin had jumped from 70,000 to 300,000 during the intervening ten years. Whereas at least 50,000 plague deaths were recorded in 1910–11, only 8500 persons died in the epidemic of 1920–21. These are satisfactory figures and show what modern prevention may accomplish against dangerous disease. It is hoped that our people may take this lesson to heart, and in future have more faith in their scientific men, for in the fight against such insidious and unseen foes as plague germs, only those experts who are specially trained can keep their presence of mind and at the same time perform their duties effectively and economically.

---

Reviews and Notices of Books.

INDUSTRIAL FATIGUE AND EFFICIENCY.

By H. M. Vernon, M.A., M.D. London: George Routledge and Sons, Ltd. 1921. Pp. 264. 12*s.* 6*d.*

The study of the human machine in this country was given a remarkable impetus by the Health of Munition Workers Committee and the work started by them has since been carried on by the Industrial Fatigue Research Board. Reports have been issued from time to time upon work completed, but the time is quite ripe for a comprehensive review of the various investigations. This task has been undertaken by Dr. H. M. Vernon, who has been responsible for much of the work done and has brought to bear upon the practice of industry a training acquired in the laboratory.

Few can be aware of the amount that has been done on the subject, more in this country than in any other. The work summarised by Dr. Vernon deals with human activity and efficiency, the attributes of sound health. It suggests that in order to maintain his health, the industrial worker must do a good day's work, expending a reasonable amount of energy over his labour; but, on the other hand, by the avoidance of fatigue his efficiency is increased. Dr. Vernon supports his statements by carefully collected facts, whether he is dealing with hours of work and their distribution within the day, or within the week, with the length of spells of work or the interpolation of rest-pauses, with limitation of output, with sickness or accidents, or with the influence upon workers of such environmental conditions as lighting, temperature, and ventilation. He claims that "experienced industrial workers unconsciously adopt habits of work which tend to the production of a maximum output with a minimum of effort." Clearly anything which will lessen the effort will increase the output. Reduction of hours may increase total output, especially when the work is chiefly dependent upon the human as opposed to the mechanical element. The energy wasted in standing about for long hours can be made productive in a day of shorter hours; the slow rate of activity adopted when hours are over-long is uneconomical, just as is too rapid a pace resulting from "drive." Dr. Vernon considers, analyses, and finally condemns overtime as uneconomical, because it slows down work on other days; thus two hours of overtime added to an eight-hour day on two days a week tends to result in the pace for every day of the week being that of a ten-hour day. He arrives at the conclusion that for manual work, such as coal-mining, a seven-hour day is reasonable; for work partly manual and partly mechanical, such as engineering, an eight-hour day; and for mainly mechanical work, such as textile manufacture, a nine or ten-hour day. The six-hour day with multiple shifts is discussed with favour as regards internal administrative economy and the outside life of the worker.

Dr. Vernon is opposed to the Saturday whole holiday, at any rate for men; two days of rest are not needed to recuperate from five days of work. The extra day has to be paid for by longer hours on the other days, and Dr. Vernon reiterates that the pace worked depends on the longest day worked. The long week-end, moreover, permits lack of practice to become so pronounced as to increase the already low output of Monday. The ideal distribution of a nine-hour day is given as three spells beginning with one of 4 hours, a second of 2¾ hours, and a third of 2¾ hours, the last two being separated by 15 minutes for tea. In a chapter dealing with limitation of output and how to detect it, Dr. Vernon has included much previously unpublished information. The effect of fatigue upon diminishing personal respect and increasing drunkenness is discussed; employers are urged to keep and pool records for a more general investigation of this important subject, and of the effects of over-fatigue and occupational environment in impairing digestion and in lowering vitality. We read with some astonishment the conclusion that fatigue has comparatively little direct effect in increasing either sickness or mortality; it is the environment of labour rather than its severity which matters. In the discussion of industrial accidents and their prevention (incidentally, this section of the book is excellent) fatigue is regarded as less likely to be a cause of accidents than speed of production, inexperience, alcohol consumption, temperature, lighting, and the psychical state of workers.

A habit of mind as a means of prevention is placed far before mechanical contrivances; attention to environment and education of workers through safety committees are strongly advocated. The question of environment—that is, factory conditions—is regarded by Dr. Vernon as more important than any other in its effect on the consideration of output, and on this point he would have us concentrate. He has put his case well and we can only regret that his conclusions are not collected in a convenient summary at the end of the book; such a summary might attract even the busiest industrial magnate to the study of a book which, if it were widely read, might bring about a second and more desirable industrial revolution.

MEDICAL EXAMINATION FOR LIFE INSURANCE.

By Thomas D. Lister, C.B.E., M.D., F.R.C.S., M.R.C.P., President of the Assurance Medical Society; Physician to Mount Vernon and Royal Waterloo Hospitals. London: Edward Arnold and Co. 1921. Pp. 168. 10*s.* 6*d.*

In view of the fact that most medical men in active practice are more or less frequently consulted in regard to life insurance, either in the capacity of medical examiner or medical referee, it is somewhat regrettable that, in this country at any rate, little if any attention is paid to the subject of insurance medicine in the medical curriculum. The problems which confront the practitioner in this connexion are entirely different from those of the diagnosis and treatment of disease with which he is more commonly concerned. In the examination for life insurance he has not only to appraise the present condition of the proposer's health, but also to consider his family and personal history critically and to make some attempt to assess expectation of life—that is, to determine whether the proposer is likely to live as long as the average of healthy persons of the same age. As referee the doctor is asked to give confidential information as to the proposer's previous health and habits, and also to express an opinion as to his prospect of surviving to the normal expectation. Life insurance medicine requires careful study, and for its application in practice a due appreciation of the responsible and confidential character of the reports required is necessary. We are not suggesting the addition to the student's statutory course of a new and compulsory subject, but only that the way to apply medical knowledge to insurance questions should be explained by teachers of experience.

There has long been a need for an up-to-date and authoritative manual on this subject, giving instruction and advice in regard to the various problems concerned, in such a way as to be helpful to the occasional examiner and to the medical practitioner asked to act as referee—that is, to report upon the health of his own patient. Dr. Lister's admirable book supplies this need exactly, and it would be difficult to commend it too highly. It deals with the theoretical considerations underlying insurance medicine only in so far as they are necessary to explain the procedures recommended, and detailed reference to statistical or actuarial considerations is wisely avoided. The information given is essentially practical, and every page reveals the author's wide experience. Dr. Lister writes so clearly and so well that what might have been a dry and technical book is most readable and interesting. Though primarily

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

EXHIBITION OF CASES AND SPECIMENS.

A MEETING of this section of the Royal Society of Medicine was held on Oct. 14th with Sir W. HALE-WHITE, the President, in the chair.

Dr. H. L. TIDY showed a case of

Diabetes Insipidus

following a bayonet wound under the left eye. The patient stated that on recovering consciousness after his wound his first sensation was thirst, and he had noticed constant thirst and polyuria ever since. It was supposed that the wound had involved the pituitary gland, but it had healed without any other complication than that for which the patient was exhibited. The patient's sugar tolerance was well up to normal, and the Wassermann reaction was negative. Various forms of treatment, including pituitary extract, had been tried without any success. Temporary improvement had followed restriction of fluids, but the patient could not tolerate this treatment.

Dr. A. FEILING inquired whether valerian had been exhibited, and Dr. TIDY replied in the negative.

Dr. FEILING and Mr. W. L. HOLYOAK showed a case of

Renal Dwarfism

in a boy, aged 12½ years, who came under observation for defective vision in the left eye. His height was 43½ in., weight 3 st. 13½ lb.; and his mental state appeared normal. The legs exhibited marked genu valgum, and both this and the defective vision were said to have come on after an attack of whooping cough at the age of 4. In the left eye vision was reduced to large moving objects only, and there was primary optic atrophy. Vision in the right eye and the visual field were normal. There has been constant albuminuria amounting to 0·25 per cent. with a few hyaline and granular casts. The cardio-vascular system was normal, and the blood pressure not raised. The Wassermann reaction was negative in both blood and cerebro-spinal fluid. An X ray of the skull showed an undeveloped sella turcica. Dr. Feiling asked for advice as to treatment of the genu valgum.

Dr. TIDY inquired whether there was a history of similar conditions in other members of the family. The answer was in the negative.—Mr. R. P. ROWLANDS said he would be adverse to any operation for the genu valgum.—Dr. F. PARKES WEBER saw no reason to connect the optic atrophy with renal disease in this case.

Dr. G. A. BACK showed a case of

Doubtful Cyst of the Left Lung for Diagnosis.

The patient, a railwayman, aged 39 years, was attacked with a sharp pain in the left side of the chest on August 15th, 1921. He continued at work for three days, and then saw a doctor as the pain persisted and he had some cough with colourless expectoration. He came to St. Thomas's Hospital on Sept. 7th, when he presented the following physical signs: dullness, much diminished breath sounds, and absence of vocal resonance and fremitus from first to fifth intercostal spaces on the left side. An X ray showed an opacity of the upper third of the left lung suggesting thickened pleura, and slight deficiency in expansion. The heart was not displaced, and there was no alteration in the voice or pupillary reactions. A blood count revealed a leucocytosis of 22,000 with 85 per cent. of polymorphs and no eosinophilia. Exploratory puncture had been performed without obtaining any fluid. He now had no expectoration and was not losing weight. Dr. Back discussed the differential diagnosis, which rested between encysted fluid or pus, hydatid cyst, or a growth.

Dr. MAURICE A. CASSIDY thought that aspiration with an ordinary serum needle was always unsatisfactory, and advised a further attempt with the largest needle obtainable, or an exploratory thoracotomy.—Dr. E. STOLKIND suggested an artificial pneumothorax and pleuroscopy as a means of establishing a diagnosis.—The PRESIDENT thought that all the signs pointed to a localised empyema probably following ambulatory pneumonia. The nature of the patient's pain suggested this.—Dr. BACK, in reply, said that in his opinion the sudden onset of the pain did not preclude a tumour, since the pain might coincide with the invasion of the pleura by a growth previously confined to the lung.

Dr. BACK also showed a case of

Chronic Pleural Effusion.

The patient, a commercial traveller, aged 41, began to suffer from a dull aching pain in the left hypochondrium and lumbar region in August, 1920. In December, 1920, he was admitted to the London Hospital, where he was X rayed for a renal calculus with a negative result. Shortly after 4 oz. of fluid were aspirated from the left pleural cavity. No tubercle bacilli were found in the fluid. He was sent to Felixstowe to convalesce, but the pain continued. In March, 1921, he was admitted to the Homœopathic Hospital, where he remained for nine weeks and the left chest was aspirated on two occasions. On the first occasion 30 oz. of clear fluid were withdrawn, and on the second occasion a similar quantity of blood-stained fluid. He said the pain was no better on discharge, and that he had some difficulty in breathing. In July, 1921, he had once a slight hæmoptysis and on July 30th he was admitted to St. Thomas's Hospital with a temperature of 102° F., when he presented all the signs of a left-sided pleural effusion up to the third rib. During three months in hospital the pain had not improved, but the temperature had only been above normal on three or four occasions. He was aspirated on two occasions, and the fluid obtained was deeply blood-stained. Some of the fluid had been injected into a guinea-pig, in which no tubercles were found after death. His weight had remained unaltered at 8 st. 2 lb. Dr. Back asked for opinions as to diagnosis.

The PRESIDENT thought that the presence of blood on no less than three occasions in the fluid was strongly suggestive of a new growth.—Dr. STOLKIND thought that in this case also artificial pneumothorax, followed by pleuroscopy, would assist in diagnosis.

SOCIETY OF MEDICAL OFFICERS OF HEALTH:

NAVY, ARMY, AND R.A.F. HYGIENE GROUP.

THE annual general meeting of this group of the Society was held at 1, Upper Montague-street, Russell-square, London, on Sept. 30th, when Surg. Rear-Admiral Sir PERCY BASSETT-SMITH was unanimously elected President of the Group for the ensuing year.

Major-General Sir W. G. MACPHERSON read a paper on

Disposal of Latrine Contents with Special Reference to Immediate Incineration.

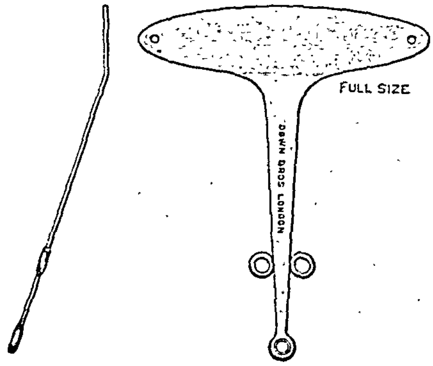
He said that the subject was of interest in civil life in connexion with holiday and other camps. The prejudice against the system of immediate or individual incineration was due to ignorance of its advantages. He did not propose to discuss recognised water-carriage systems, nor to detail the different kinds of camp latrines and incinerators, but only to review these briefly in discussing the special differences between immediate incineration and indirect methods of disposal. Sir W. Macpherson described the appalling conditions produced by prolonged use of the shallow and deep trench systems, unless under constant and careful supervision. War experience had shown that wherever possible the most satisfactory method of disposal was by incineration. There were two recognised methods of disposal by incineration: in one the latrine contents were carried in buckets or filth carts to incinerators at some distance from the latrines, and in the other threads through the mass, to get evidence of what happens as the bullet passes through. He found that the explosive effect radiated from the track to a distance varying inversely as the square of the density of the gelatin, four times as far in 5 per cent. gelatin as in 10 per cent., sixteen times as far in 5 per cent. as in 20 per cent., and so on. Similar principles seem to hold for the tissues of the body. The influence on treatment is clear. The track of a pistol bullet may only need superficial cleaning, but the track of a high-velocity bullet needs wide opening up. Tough tendons and aponeuroses are likely to be torn out of the tissues by the bullet which pierces them. In soft tissues, liver, kidney, &c., the damage is very extensive. Owing to the low viscosity and density of the blood, damage spreads far along the vessels, and there is special risk of thrombosis, secondary hæmorrhage and aneurysm, so that if a bullet passes near a large vessel the latter may require to be tied well away from the track. This paper merits the attention *of all military surgeons*.—Lieut.-Commander C. S. Stephenson, U.S.N., contributes a thoughtful paper on "Syphilis and Venereal Disease, a Service Liability." He notes that stopping men's pay for venereal disease leads to concealment of disease and at times to injustice, and concludes that laws and penalties against venereal disease are unwise and ineffective. The only practical law will insist on prophylaxis, punishment following disobedience; in other respects venereal patients are to be treated exactly as others, but means of infection are to be kept away from the men, as was done during the war.—Lieut. D. F. Elmendorf, U.S.M.C., examined 40 men of the American force in Germany for Vincent's angina and found 35 of them were carriers; examination was made by dark-ground illumination.

JOURNAL OF LARYNGOLOGY AND OTOLOGY. July and August, 1921. Vol. XXXVI., Nos. 7 and 8.—The July number contains a study by S. Mygind of Copenhagen of the reflex movements of the facial muscles elicited by rotation and apparently due to vestibular stimulation; as they are not obtained after the age of six weeks, they do not appear to possess a direct clinical value. This is followed by a series of statistical tables from the ear and throat department of the Edinburgh Royal Infirmary for the years 1919 and 1920; it gives the number of cases of the different diseases treated in each year, occupies ten pages, and would have been more interesting if it had been accompanied by a commentary.—Mr. E. B. Waggett describes an interesting case of a large *chondroma growing from the cricoid cartilage* successfully removed through a lateral external incision.—Dr. James Don relates a case of encephalitis lethargica in which the diagnosis was obscured by chronic bilateral aural suppuration; a radical mastoid operation was performed on the right side, without affecting the general condition, and the patient eventually recovered. ——To the August issue, Sir William Milligan contributes a short note on diathermy in inoperable cancers of the throat; Dr. Logan Turner gives an account of six cases of vocal cord paralysis secondary to malignant tumour of the mamma, with a careful description of the anatomy of the lymphatics concerned.—Dr. F. G. Wrigley describes a case in which the cavernous sinus probably became thrombosed secondarily to an otitis media, and in which the clot was expelled on opening the healthy lateral sinus with eventual recovery.—Dr. Albert Gray gives a summary of various theories of hearing: he disagrees with Wrightson's theory, as it involves the final analysis of tones in the brain, and favours Helmholtz's theory, which embodies the principle of "sympathetic resonance" and analysis in the cochlea, with a modification of his own; agreeing that the basilar membrane vibrates over a large area in response to a given note, he argues that it is the point of maximum vibration which determines the sensation of pitch.—The reports of societies' proceedings have been greatly abridged in order to make up the arrears into which they had fallen; they are still six months behind.

New Inventions.

HARE-LIP SURGERY: A SUGGESTION.

CASES of hare-lip and of the more common congenital abnormalities are seen in considerable numbers among our out-patients to-day. The after-results of operation are often deformity or disfigurement, common troubles being a plain notch at the lower end of the operation scar, and a certain amount of keloid thickening of the scar. This is no doubt caused by upward contraction of the scar tissue, occurring in this region because of the large amount of fibrous tissue entering into the construction of the upper lip. A post-operative straight lip is a rare occurrence. The mechanical means described below are devised to overcome this contracture, and, as it were, to "hyperextend" the seat of operation. The angle of incision and the point of juncture of the two halves of the lip are best left to the individual surgeon. It is the practice at present to bring the lip together by means of skin sutures. This I feel sure plays a great part in causing the prominent after scar. Approximation of the parts can be brought about as well by Czerny sutures from the mucous side of the lip, causing little or no tension on the scar. I venture to suggest these sutures for general use in hare-lip surgery. As a mechanical means of overcoming the contraction, I use the splint illustrated immediately after operation. Made of silver, the instrument is small and easily handled. It has a main shield-shaped body, carrying two small needle-holes at the extremities, and a projecting arm with three small rings attached as suture anchors. This arm is bent away from the main body at an angle of 15°, thus precluding any interference with the feeding of the patient. The splint is applied immediately after operation. Thin silkworm gut is used as suture material. The splint is sutured to the upper lip through the two holes in the body of the instrument. A circular suture is passed through the lip at the point of juncture, and two sutures at each side at a distance of a quarter of an inch. These are fastened to the rings on the projecting arm, and a slight amount of tension applied, thus pulling forward and downward the lip at the site of operation. The splint is kept applied for eight to ten days after the operation. The continued tension on the lip causes a curve downwards, which, allowing for subsequent contracture, leaves a presentable lip and no unsightly notches.



The instrument has been made for me by Messrs. Down Bros.

Harley-street, W. L. SAMUELS, M.D. Sheff.

THE LATE DR. REGINALD LAWSON MOSLEY.—Dr. R. L. Mosley, who died on Oct. 6th at Shaldon, South Devon, in his sixty-fifth year, was a graduate of Dublin University, where he graduated B.A. (first-class honours) in 1879 and M.B. two years later. In 1880 he became L.R.C.S.I. and L.M. of the Rotunda Hospital, Dublin.

The facts seemed to show that intravenous injection of salvarsan reinforced by mercury was the best post-natal way of treating congenital syphilis; that the younger the patient the greater the probability of cure; and that a case should only be pronounced cured when the Wassermann reaction has been proved to remain negative.

Dr. ETHEL CRAWFORD read a paper on Sulfarsenol in Congenital Syphilis.[1]

Prof. C. H. BROWNING made a communication on

The Anti-Syphilitic Action of Arsenical Compounds in relation to their Constitution.

He said that although there were many substitutes they were similar in chemical constitution to salvarsan, although there was an unfortunate diversity of names. Though atoxyl, which is a stage in the synthesis of salvarsan, has a serious effect on the optic nerve, there was no ground for the belief held by some ophthalmologists and others that salvarsan has a harmful action on the nervous system. Atoxyl bore a relation to salvarsan that might be compared to the relationship of alcohol to sugar. There was, however, danger in allowing solutions to remain exposed to air for long, as the solutions underwent decomposition; and there was also some danger from using large quantities of fluid at one time. Nowadays improved methods of administration and improvements in the drug itself had eliminated these risks. Salvarsan substances were not clearly defined chemical entities. They were colloidal substances, incapable of absolute purification, and consequently impurities appeared in the various preparations. These modified solubility, reaction after administration, &c., and might possibly modify the toxicity of the drug in the body. Thus it was impossible to test the activity of any of the salvarsan substances in vitro. The tests should be conducted in vivo by a disinterested party. The relative efficiency of the members of the group was important. The new substances were more easily given than the old, but, on the whole, less efficacious. In order to avoid danger the least toxic substance was usually employed, even though by reducing toxicity the therapeutic efficiency was also reduced. Old salvarsan produced a febrile reaction. When years ago an inquiry was made into the history of syphilitics in the Austrian army it was found that those who had developed a febrile reaction after infection did not develop general paralysis. To check the efficiency of treatment by the disappearance of clinical symptoms was not sufficient; biological tests such as the W.R. and the precipitation tests should be used.

Dr. J. R. C. GREENLEES read a paper on

The Ante-natal Treatment of Congenital Syphilis.

He said that post-natal treatment of congenital syphilis attacked the disease too late. The focus of the infecting spirochætes was probably the placental tissue and therefore treatment should aim at prevention of their development there and their spread to the fœtus. Dr. Greenlees quoted statistics to show that ante-natal treatment with mercury and iodide of potassium had not been very successful. On the other hand, 15 cases treated in the Royal Hospital for Sick Children, Glasgow, where ante-natal treatment was carried out with arsenical compounds and mercury, all showed successful results, some of these cases being followed up for as long as seven years.

Dr. LEONARD FINDLAY made a communication on

The Ravages of Congenital Syphilis: How to Combat them: A Plea for Notification.

He said that the foregoing communications showed that ante-natal treatment was *the* treatment par excellence. Prophylactic was beyond question better than curative treatment. The ease of the ante-natal method of treatment and the avoidance of the pain and misery many young syphilitics underwent in the course of the curative treatment were striking recommendations in its favour. Dr. Findlay criticised statements recently made to the effect that congenital syphilis was becoming less severe in its manifestations. He strongly advocated the application of the ante-natal method of treatment by the general practitioner, and gave his opinion that with the Wassermann test available and easy administration of the new salvarsan preparations there was no necessity for the special venereal clinic nor for the so-called venereal specialist in the case of syphilis. In conclusion he dwelt at length on the desirability of making syphilis a notifiable disease with particular regard to its influence on infantile mortality.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE opening meeting of the fortieth session of this Society was held at the West London Hospital on Oct. 7th, when Sir GEORGE LENTHAL CHEATLE delivered as his presidential address—

A Study of Breast Cancer in Relation to the Cancer Problem.

He said he had always been deeply impressed with the fact that any sufficient stimulus—mechanical or chemical—will cause the egg to awake and divide. If the stimulus was a living one it was probably of a physico-chemical nature. There were many factors influencing cell division—e.g., age, sex, heredity, &c. He particularly emphasised the importance of life-wear and nerve influence on the epithelial cells in this connexion. He did not consider that corset-pressure was an important factor in breast cancer. The traumatic mastitis that might result rapidly disappeared on removing the cause. But he showed how a diffuse, benign, desquamative hyperplasia of epithelium induced cyst formation in ducts and acini, or in ducts alone and acini alone. He believed the cause of the hyperplasia to be due to an irritant within the ducts or acini respectively. The irritant might enter the breast by the open orifices of the ducts on the surface of the nipple. He did not believe that the inflammation sometimes seen outside the ducts was the cause of the hyperplasia within. This was, in many cases, secondary and due to the irritant leaking out here and there, and causing isolated collections of lymphocytes.

The formation of cysts meant stagnation of contents, and as they caused irritation their action may remain undisturbed over long periods. Hence, two possible events might occur: (1) The formation of uni- and multi-radicular papillomata (simple); (2) the development of definite cancer (papillomatous or "laciform"). All of these he described as beginning in duct cysts, and in more than one part in the same breast. The multi-radicular papillomata were often malignant, and for this reason were the more important. The ampullæ of the ducts were a favourite site for their growth. The "laciform" type of duct cancer was very malignant and might be pure, or mixed with the papillomatous type. Cysts containing papillomata or cancer were first small cysts. The epithelium of the large cysts is so atrophied and degenerated that it is no longer capable of responding to the stimulus of further irritation. Many surgeons were saying that because they had never seen cancer in breasts from which they had removed cysts, therefore cancer in cysts must be rare. There was nothing in that statement. He had had a breast sent him for examination which had been removed for cysts only. In it was a multi-radicular papilloma, and near it a focus of cancer invading the fat around it. Again, if surgeons removed cystic conditions they had removed possible sites of cancer. The small cysts were the most dangerous as in them the epithelium was active.

SOUTH-WESTERN OPHTHALMOLOGICAL SOCIETY.—The next meeting of this society will be held on Monday, Oct. 24th, at Bristol Eye Hospital. At 2 P.M. cases will be shown, and Mr. Ransom Pickard will read a paper on the Development of Normal and Abnormal Disc Cups. At 7 P.M. there will be a dinner at the Grand Hotel, Bristol.

---

[1] See THE LANCET, Oct. 1st, p. 700.

villages where this abortive outbreak occurred, as soon as the climatic conditions became favourable cases at once reappeared and a more or less violent attack followed. Hence, these late infected centres acted as reservoirs of infection during the "off season" and when conditions for the spread of the disease recurred they formed centres from which dissemination of the disease into the neighbouring villages would take place. These facts have, of course, been well known to epidemiologists for a considerable time, but Major **KUNHARDT** and his assistant went further; they argued that if something could be done for these late infected villages during the off season, recrudescence might be prevented; and conversely that it was useless to attempt any measures in the villages that had passed through the ordeal of an ordinary violent epidemic. A large tract of country in the Deccan comprising parts of the districts of Poona, Ahmednagar, Satara, and Sholapur were selected for experiment, a careful study of the plague figures village by village being carried out. During two years 458 villages were infected. Of these 218 were thrown out at once as quite unlikely to "carry over." At a more detailed examination another 189 were also discarded. It was thus decided to concentrate operations on 50 places—that is, about 10·9 per cent. of the total number infected. The work on these 50 places consisted mainly of a very determined attempt to rid the places of rats. Subsequent events showed that of these 50 places, 20 carried plague over to the following season in spite of these measures. Out of the 407 places excluded as being unlikely to carry over the disease, only three (all in the second year) continued to harbour the disease. In all three of these special circumstances existed explaining this. From this work the following conclusions are legitimate. First the method of recognising centres of infection that are likely to carry over the off season is useful, though admittedly crude. Second, that the failure to eradicate plague was due to the non-success of the rat campaign, and thirdly that the off season centres of infection are more important than importation from without.

A second important paper by the same authors is published in the *Journal* giving in detail the results of their experiences on rat extermination. The actual conclusions of this paper have been previously published. Two outstanding points may be referred to—namely, that hydrocyanic acid gas as a means of exterminating rats in the ordinary native house was a failure, and second the best rat poison used was found to be barium carbonate. Thus it will be seen that the campaign to rid the area of infection, so admirably conceived and thoroughly carried out, broke down for the simple reason that we cannot free the Indian village of rats successfully by any means at our disposal at present. Work is still going on which will sooner or later bear fruit. Had it not been for the upset of the services in India during the war, probably success in this direction would have crowned the efforts of the workers by this time. The problem of ridding large countries of plague infection is an extremely complicated one. The difficulties, as we have already shown, of rat extermination in a tiny little area like one Indian village are enormous. Armchair critics of the Government of India in this country sometimes talk in a light way about keeping rats out of human habitations by constructing rat-proof buildings. These individuals do not appear to recognise the fact that practically every home is a grain store as well, and that it is impossible, at present, to keep grain in bulk outside of villages and out of human habitations. Something may be done to educate the people to see the disadvantages of harbouring the rats in their houses, but the East moves very slowly, and the mud house common in many parts of the country is the only one that the inhabitants can afford, and it possesses certain advantages over any other type in a climate such as India. Even when the immediate difficulties of rat campaigns have been overcome there are still other problems in connexion with plague that have to be investigated, such as the way in which the traffic influences the spread of the disease by importation. We publish this week (see p. 853) a preliminary report upon the Manchurian plague epidemic of 1920–1921 by Dr. **WU LIEN TEH**, the chief executive officer of the Chinese Plague Prevention Service. The full report will not appear until next spring, but the findings published are interesting, and have a close bearing on many of the problems present in India.

◆

Preventive Surgery.

THERE are certain periods of revision through which every art, nation, business, or individual must pass at times; periods in which the results of previous work are surveyed in a critical spirit, and plans for the future are considered. Through such a period of reconstruction surgery may now be passing. The last 40 years have been marked by progress on a truly extensive scale, till to-day there is no part of the human frame safe from surgical enterprise, and few diseases for which surgical remedies have not been attempted, or at least suggested. Yet, apart from the notable advances made during the war in thoracic surgery and the plastic surgery of the face, the closing years of this period have seen few really new realms explored and few startling innovations brought to light, while many of those of a former generation have been abandoned. The surgical advance inspired by **LISTER** has reached a position in which its leaders consider it wise to consolidate; and if in the process some of the furthest salients have proved to be untenable, there is about the whole position a security which is reassuring to the spirit of the mass of workers. Surgical procedure has become standardised and simplified, and the tendency of the more important writings that have appeared of late has been critical rather than intrepid. There is a general tendency among writers to admit that nothing startlingly new is likely to appear, and to look for improvements in surgery rather to new methods than to new principles.

An article by Mr. **PHILIP TURNER** on the Principles of Preventive Surgery, published in a recent number of the *Guy's Hospital Gazette*, furnishes an example of a desire on the part of surgeons to look at their profession from a broadly different standpoint from that taken up even 20 years ago. Mr. **TURNER** discusses the great part which preventive medicine has come to play in our national life, and seeks to apply the preventive principle to matters surgical. This is not an easy task. Surgery deals essentially with abnormalities already established, steps in where prevention has failed; and, unless we are to advocate the routine performance not only of circumcision, but of tonsillectomy, cholecystectomy, gastro-enterostomy and appendicectomy, and to forestall the ills which these operations now cure, it is hard to conceive a place in our text-books for preventive surgery as a special branch, or to contemplate the addition of a "D.P.S." to the diplomas of an already over-examined profession. If the considerations put forward by Mr. **TURNER** are studied—and they well repay study—his views on intended for the occasional examiner and the medical referee, to whom it should be invaluable, there can be few connected with life insurance work who would not derive useful information and counsel from its perusal.

NEUROLOGY.

Clinical Examination of the Nervous System. By G. H. MONRAD-KROHN, M.D. Christiania, M.R.C.P. Lond., M.R.C.S., Lecturer in Neurology at the Royal Frederick University, Christiania. With a Foreword by T. GRAINGER STEWART, M.D., F.R.C.P., Physician to Out-patients, National Hospital, Queen-square. London: H. K. Lewis and Co. 1921. Pp. 135. 6s.

Dr. Monrad-Krohn's guide to the routine examination of the nervous system represents, we suppose, about the minimum requisite to cover the ground in a satisfactory manner, and yet it runs to over a hundred pages. We have gone over this little unpretentious précis of routine examination paragraph by paragraph and have no hesitation in warmly commending it to the student and the practitioner. It is really surprisingly comprehensive in view of its small compass. The inclusion of the Binet-Simon tests and of other psychological and psychiatric investigations adds to the all-round usefulness of the book, which should be in the pocket of every neurological student, at the bedside, or in the out-patient room, until such time as the routine examination of a nervous case has become second nature to him.

Diseases of the Nervous System. Third edition, revised. By H. CAMPBELL THOMSON, M.D. Lond., F.R.C.P., Physician to the Department for Diseases of the Nervous System, and Lecturer on Neurology, Middlesex Hospital. London: Cassell and Co. 1921. With 11 colour and 12 black-and-white plates, and 120 figures in the text. Pp. 566. 15s.

THE third edition of Dr. Campbell Thomson's textbook of nervous diseases appears after an interval of some six years. Incorporated in the book will be found paragraphs dealing with certain recent acquisitions in neurology, the result to a large extent of war experiences. Some modification has also been introduced into the chapters dealing with the neuroses and psychoneuroses, whereby they are brought more into line with the most modern teaching, though compulsion and anxiety neuroses receive a disproportionately small consideration as compared with hysteria and neurasthenia. Dr. Campbell Thomson's text-book maintains its position as embodying a sound, practical, and thoroughly up-to-date presentment of neurology for student and practitioner.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXIV., No. 4. Pp. 369–479. October, 1921.—Studies on the Pathology of Pneumococcal Infections of the Human Lung, by R. R. Armstrong and J. F. Gaskell. The authors have reinvestigated some points in the pathology of pneumonia, using a gelatin-embedding method for histology which preserves the natural relations of the parts more perfectly than the usual paraffin process. They believe that the pneumococcus invades the lung (*a*) by the air-passages, causing lobar or broncho-pneumonia according to the virulence of the organism and the resistance of the host, the essential histological lesions being the same in both cases; (*b*) by the blood stream, giving scattered miliary lesions without any exudate of polynuclear leucocytes; (*c*) by the lymphatics, giving rise to an uncommon type of relapsing pneumonia in children.—Digestion of the Œsophagus as a Cause of Post-operative and other Forms of Hæmatemesis, by J. H. Pringle, L. T. Stewart, and J. H. Teacher.—The Viscosity of Syphilitic Serum, by J. Holker. The viscosity of sera giving a positive Wassermann reaction does not differ very definitely from that of normal sera, but it increases a good deal more on keeping and on dilution with salt solution.—The Standardisation of Vaccines, by J. Holker. The author's opacimeter method gives accurate results with little labour.—Group Agglutination of the Gonococcus, by S. H. Warren. No evidence of groups was found.—Absorption from the Peritoneal Cavity, by C. Bolton. The peritoneal cavity is drained chiefly by the diaphragmatic lymphatics into the mediastinal lymphatics to the right lymphatic duct, and by intrathoracic anastomoses to the thoracic duct. Particles up to the size of red blood corpuscles pass easily between the endothelial cells into the lymph, and the chief force is supplied by the respiratory movements. An important paper which should be consulted for the full results.—The Blood and Blood-vessels in Guinea-pig Scurvy, by G. M. Findlay. In experimental scurvy there is swelling and degeneration of the capillary endothelium which retards the blood flow and leads to local congestion; red cell counts of peripheral and heart blood are widely different.—Experimental Scurvy in the Rabbit and its Effect on Antenatal Nutrition, by G. M. Findlay. As is well known, rabbits deprived of antiscorbutic vitamin do not show any very marked signs of scurvy; the offspring, however, have hæmorrhages at the joints and in the internal organs.—Studies in Heterophile Antigen and Antibody, by T. Taniguchi. Further researches into this highly complex technical subject which must be studied in the original.—Blood-platelet Antiserum, by S. P. Bedson. The author prepared antisera by inoculating rabbits with the blood platelets, leucocytes, red corpuscles, and serum respectively of guinea-pigs, and examined their relative agglutinating action on the three particulate antigens with a view of elucidating the genetic relationships of the formed elements of the blood. On this basis platelets are certainly distinct from leucocytes, but the distinction between platelets and red cells is not so clear nor is that between red cells and leucocytes.—A Case of Erythema Nodosum from which an Organism Resembling *B. influenzæ* was Obtained from the Blood, by E. Emrys Roberts.—Two Cases of Typhus Fever in which *B. proteus* was found in the Cerebro-spinal Fluid, by J. M. Anderson.

IN THE MILITARY SURGEON for September, Colonel L. B. Wilson, U.S.M.C., discusses the Dispersion of Bullet Energy in Relation to Wound Effects—in other words, the explosive action of high-velocity bullets. The wounding effect of a projectile depends on its mass and on the square of its velocity, and the smooth-bore bullet, though heavy, was slow. Rifling was invented long ago, but at first it only made shooting more accurate; not until about 1725, when the greased patch or wad was introduced, which conquered windage and prevented the leading of the grooves, were firearms revolutionised. Then bullets gained velocity sufficient to give large animals fatal wounds. The rifleman could now use larger powder charges, and muzzle velocity increased from 500 to 1500 or 2000 foot-seconds. This high-velocity missile, says Colonel Wilson, was a very potent factor in the winning of the colonists' war for independence. In the Civil War of 1862, speed of fire seemed so very important that the question of high velocity rather dropped into the background. Kocher of Berne was the first to publish (1875) an account of experimental investigation of the wounds produced by high-velocity projectiles. Bullets with muzzle velocity of 2000 f.s. produce at short ranges explosive effects, which were occasionally seen in the Spanish-American War (18[illegible] bullets of 3000 f.s. produce them at longer [illegible] True explosive bullets, often heard of, are rare [illegible] of the author has examined thousands [illegible] ved cartridges, but only found one explosive [illegible] the was taken from a German ammunition [illegible] iero Argonne. The explosive effects so often [illegible] occur due to the high velocity of the bullet [illegible] Wilson has made a great many [illegible] effects of high-velocity bullets [illegible] standard range of 50 feet [illegible] with gelatin of varying [illegible] have been varied by [illegible] the face of the block [illegible] reconstructions to scale (magnification of 100) of the eye and adjacent parts of the brain in human embryos up to the third month. The processes of outgrowth of the optic vesicle and its subsequent invagination to form the optic cup were clearly seen, while the formation of the choroidal fissure, always a stumbling block to students and difficult to show in a drawing, was made plain at a glance. The separation of the lens vesicle from the ectoderm was well shown in the model of the 7·5 mm. embryo, in which also could be seen the earliest stage of development of pigment in the outer layer of the optic cup. Given a series of models such as these, the path of the lecturer would be considerably smoothed, and the student, whether of ophthalmology or anatomy, would acquire a greater interest in a subject at present often obscure and depressing.

DIGESTION OF THE ŒSOPHAGUS.

POST-OPERATIVE vomiting of black material or actual hæmatemesis is a well-known symptom, and one of grave import. Mr. J. H. Pringle, Mr. L. T. Stewart, and Prof. J. H. Teacher, of the Royal Infirmary, Glasgow, have recently shown[1] that in some of these cases the blood comes not from the stomach but from the œsophagus, which is ulcerated and digested by the regurgitation of stomach contents or by a failure to clear the œsophagus of digestive liquids after actual vomiting. The lesions vary in severity from superficial erosions to the destruction of the wall of the œsophagus and even of the surrounding tissues, and evidence has been found of spontaneous healing. The practical indication is obvious—that the œsophagus should always be washed out after vomiting—and we find here the explanation of why our mothers always gave us a drink of water after we had been sick.

PREGNANCY FOLLOWING IMPLANTATION OF OUTER END OF ONLY REMAINING TUBE.

IN the *Johns Hopkins Hospital Bulletin* for September Dr. H. N. Shaw has reported a remarkable case in which pregnancy followed implantation of the outer end of the only remaining Fallopian tube after resection of a cornual pregnancy. A woman, aged 36 years, was admitted on Oct. 3rd, 1919, complaining of irregular menstrual periods. She had been married six years, and had had one child and two miscarriages—one nine months after marriage at three months, and the other in March, 1919, at two and a half months. A regular period apparently occurred four weeks before admission. A few days before admission irregular bleeding began. This increased in amount, but no large clots were passed. On examination a median abdominal scar was found. The uterus was apparently normal in size and position, but at the left cornu was a rounded mass several centimetres in diameter, not tender, and rather soft and fairly movable. Left tubal pregnancy was suspected. Laparotomy was performed by Dr. Cullen. The old abdominal scar was excised. On opening the peritoneal cavity an adhesion between the uterus and scar was found. It was clamped, cut, and tied. (In 1918 at another hospital the uterus had been suspended and the right tube and ovary removed.) In the left uterine cornu was a tumour 5 by 4 cm., on the median side blending with the surface of the uterus and on the outer side continuous with the tube—undoubtedly a cornual or interstitial pregnancy. The tube was temporarily clamped at its cornual attachment, and the cornu resected, leaving a raw area 4 by 2 cm. at the uterine attachment. The Fallopian tube was drawn into the cornu so that its inner end lay in the uterine cavity. The wound was then approximated. The excess of bladder peritoneum was drawn over the raw area to prevent adhesions. After the operation the fimbriated end of the tube which lay free was about 1 cm. long. A cigarette drain was placed in the lower end of the abdominal incision, which was closed. Recovery followed. Sections through the cornual pregnancy showed in the centre of clot an early placenta and typical chorionic villi. In March, 1921, the patient was confined at seven months. There was marginal placenta prævia with a breech presentation. The child was born dead. Although from time to time the inner end of the resected Fallopian tube has been inserted into the uterus, Dr. Shaw has been able to find recorded only one similar case. For years Dr. Cullen has been teaching at the Johns Hopkins Hospital the utmost conservatism in dealing with pelvic conditions during the child-bearing period. Wherever possible he has preserved the menstrual function, believing that the unsexing of a woman in early life is more deleterious than the possibility of a second abdominal operation. In this case the logical procedure seemed to be removal of the tube, but the saving of the outer portion and its insertion into the uterus proved to be worth while. As the patient is still under 40, the possibility of other pregnancies remains.

DUODENAL FISTULÆ AFTER RIGHT-SIDED NEPHRECTOMY.

IN a recent number (Oct. 1st) of the *Wiener medizinische Wochenschrift* devoted to urology, in which sympathetic reference is made to the late Prof. Zuckerkandl, Dr. E. Felber gives an interesting account of the occurrence of duodenal fistulæ following right-sided nephrectomy. He discusses the anatomical relations of the right kidney and duodenum, and says that the normal variation in the actual position of the duodenum does not affect the intimate relationship of the second or descending part of the duodenum with the renal pedicle. Inasmuch as the peritoneum does not envelop the duodenum but only covers its anterior aspect, injuries to the intestine may occur without coincident injury to the peritoneum. The literature contains several references to duodenal injury in right nephrectomies, and nearly all these cases have resulted in the death of the patient from inanition.

Felber quotes a recent case of his own in which tuberculous disease of the right kidney called for a nephrectomy, which was performed by the late Prof. Zuckerkandl. The subcapsular operation was decided upon owing to widespread perinephric thickening. Two clamps were placed on the renal pedicle; the distal of these slipped, and owing to the trauma inflicted by it upon the structures of the pedicle, there was a severe hæmorrhage. The kidney was removed, and the bleeding pedicle secured and ligatured. On the tenth day the dressings were found saturated with contents of the upper portion of the small intestine; the jejunostomy performed four days later with a view to controlling the patient's inanition availed little, and death occurred ten days afterwards. The course of this case is explained by the assumption that the ligature on the renal pedicle included an area of the duodenal wall, the fistula developing owing to necrosis of this portion of the intestine.

W. J. Mayo reports three similar cases, in which the pedicle was infiltrated either by inflammatory or neoplastic processes. Hæmorrhage was encountered in each, and clamps had to be left on the pedicle at the close of the operation. All three developed duodenal fistulæ, with rapidly fatal results. Legueu and Pousson quote similar cases with the same unfortunate ending.

Payr reports one case of unusual interest. A woman, aged 31, had a right nephrectomy for a pyonephrosis. A small fistula remained after healing of the wound, and proved to be most intractable, defying all efforts to close it. Eventually the track was injected with bismuth paste with a view to X ray photography. A surprisingly large amount of bismuth was injected with but little pressure. The plate revealed the presence of the bismuth in the small intestine. Payr extirpated the fistula and repaired the duodenum with a three-tier suture. Recovery ensued, which the patient owed to the fact that intestinal contents did not pass out through the fistula.

It is evident that injuries to the duodenum usually occur in those cases in which difficulty is experienced in ligating the renal pedicle, and the surgeon is confronted with a serious hæmorrhage in a confined space. But there are other cases in which such pathological

THE LANCET.

LONDON: SATURDAY, OCTOBER 22, 1921.

The National Insurance Act.

THE Minister of Health met the deputation from the Insurance Acts Committee of the British Medical Association last week, and informed them of his intention to act on a decision of the Government and to reduce the present capitation fee paid to insurance practitioners from 11*s.* to 9*s.* 6*d.*, the alteration to take effect in the new year. Sir ALFRED MOND, in pointing out the necessity under which the Government lay to make a severe revision of all possible expenditure, admitted that he found the position of his Ministry an unenviable one, considering the beneficent health operations lying immediately ahead, but he relied on the patriotism of medical men to acquiesce in the lessened payment. He certainly made it clear that the reduction proposed has no other object than economy, for at the time of announcing the reduction he spoke in high terms of the services rendered by practitioners on the panel, whom he defended, after personal investigation of the facts, from the widespread and sometimes bitter attacks on their work which had appeared in the lay press. In spite of which Sir ALFRED MOND felt himself compelled to propose a reduction in the scale of remuneration, and to do so in face of the fact that an independent body of arbitrators had arrived in March of last year at the present figure as a fair one.

It having been explained that the deputation of the Insurance Acts Committee was in fact an Executive Committee of a Representative Conference shortly to take place, before which body Sir ALFRED MOND'S proposition would be placed, the meeting was adjourned to give the deputation the opportunity of considering the situation privately. After the adjournment Dr. H. B. BRACKENBURY, as spokesman for the deputation, put forward the views which it would be necessary to lay before the Conference. He pointed out that to call on the medical profession to surrender on patriotic grounds a large annual sum of money which had recently been found to represent fair remuneration was illogical if the reply to such a patriotic call resulted in rendering the national medical service not so good or so effective as at present; and he added that no exact data are available as to the amount of labour involved in panel work, though at the present figure of 11*s.* there was, he thought, risk lest the service should not be stable, and keep intact its large membership of able practitioners. From the moment when it became clear that the remuneration of panel practitioners would probably be made the subject of early reduction, we have pointed out in these columns the existence of this danger; we are sure that it is real, and that if a too thorough or too hasty policy of economy be pursued the loss of practitioners from the panel may include some very valuable persons. Until the data are available, whose absence Dr. BRACKENBURY alluded to, it will be difficult to persuade practitioners that the reduction is fair. The Federation of Medical and Allied Societies is in cordial agreement with Dr. BRACKENBURY in asking for information, and has for some time placed in the forefront of its programme the securing of an inquiry into the working of the Acts as being a condition necessarily precedent to arriving at full comprehension of what is being done, how well or ill it is being done, and how far the payments made are in fair correspondence with the services rendered.

In reply to Dr. BRACKENBURY'S representation Sir ALFRED MOND hoped that the proposal of the Government when placed before the Conference would be accepted, as he was not in a position to haggle, but he stated that an inquiry into panel work was about to be made, which would cover all the ground and be made without prejudice. Does this mean that the new figure is temporary? The Conference will be well advised to think of this point, for it is a most important one. A very real source of trouble to practitioners, arising out of the proposed reduction of panel remuneration, is the upset that may be caused in arrangements already entered upon. Practitioners, reckoning reasonably upon a certain income, have made plans for the taking of premises, for the education of children, and so on, any of which may have to be modified sensibly under a heavy reduction in the scale of remuneration. So vexatious an element of uncertainty ought to be eliminated, at any rate for a substantial period, in any new arrangements. Referendum papers have now been issued by the British Medical Association, asking for the views of practitioners as to the acceptance of a capitation fee of 10*s.* and the advisability of refusal to serve at the reduced fee of 9*s.* 6*d.* The conclusions of the Conference will not be available for publication in this issue of THE LANCET.

◆

The Spread of Plague.

THE news that two or three violent recrudescences of plague have occurred in some parts of India, and that some of the Australian ports appear to have been recently re-infected from outside, naturally suggests the question as to whether we are really any nearer coping with epidemic bubonic plague than we were 20 years ago. The main facts concerning the spread of plague are, of course, well known to everybody; there is no necessity to repeat them here. Quite recently a very important report has been published which may be described as the first real attempt on a large scale to eliminate plague infection from a given district. This is contained in a paper by Major KUNHARDT and Asst.-Surg. CHITRE in the *Indian Journal of Medical Research.* It should, however, be mentioned that a reference to this work has appeared in THE LANCET before, but owing to the war the full and detailed report has been considerably delayed. The work was carried out in 1914, 1915, and subsequent years.

The general plan of campaign to be adopted was something as follows: From a careful study of recrudescences of the disease in villages it was observed that when a particular village was infected in the "plague season" a violent epidemic resulted, but there appeared to be no tendency for the disease to recur in future years unless re-importation of the virus occurred. Should a village be infected at the very end of the "plague season" an abortive epidemic only is the result; this occasions a certain amount of rat mortality and a few human cases, but such a mild attack in no way resembles the classical picture of a plague outburst. It was also observed that in those within eight days from the date of the appearance of the initial case of the outbreak. In addition there were 11 secondary cases. Inquiry showed that of these 33 primary cases 28 had definitely eaten suspected food, certain "head-cheese," a form of brawn, and the other five had eaten beef bought and served at the time when the suspected brawn was purchased. Circumstantial information from certain individual cases shows clearly that the source of infection was the substance called in the report "head-cheese." No samples were available for bacteriological examination, but the food was prepared and sold by the proprietor of the meat market and his wife. It was ascertained that the wife had been ill, for a period of approximately four days, about three weeks before the outbreak. She assisted in preparing the suspected food two days before it was placed on sale. It was not found possible to examine her blood serologically, so the presumptive evidence that she was the cause of the outbreak could not be tested.

The little outbreak is of interest from two points of view. One is that recorded outbreaks of paratyphoid fever from contaminated food are still comparatively rare. The chief point of interest is the light it throws upon food-poisoning outbreaks. The prevailing German view, one also largely followed in America, is that the food-poisoning bacilli of the *B. aertrycke* or *B. suipestifer* types are identical with *B. paratyphosus B*—i.e., in other words, that the same bacillus may at one time cause paratyphoid fever, at another an attack of food poisoning. In the present outbreak, although an article of food was infected, apparently of similar nature to the foods which do convey food-poisoning bacilli, the resulting outbreak was paratyphoid fever, and did not show the clinical features of food poisoning. There was some, but not conclusive, evidence that infection originated from an unrecognised human case of paratyphoid fever and the infection bred true. The cases were all of one type, supporting the conception that *B. paratyphosus B* is a different strain not only serologically but in its ætiological functions from *B. aertrycke* and other bacteria associated with food poisoning, the one type causing paratyphoid fever only, the latter food-poisoning infections only.

POROKERATOSIS.

ACCORDING to Dr. Carroll S. Wright,[1] instructor in dermatology and syphilology at the University of Michigan Medical School, who reports an illustrative case in a man aged 40, porokeratosis was first described simultaneously by Mibelli and Resphighi in 1893. Since then not more than 60 cases have been recorded, the condition being particularly rare in the United States. In spite of the numerous theories that have been advanced the ætiology of the condition is still entirely unknown. Heredity undoubtedly plays a part, as was shown by two of Mibelli's cases, in which a brother and sister were affected, and has since been illustrated by many other cases, including Dr. Wright's, in which the grandfather, father, and a daughter of the patient were affected. The dermatosis may begin at any age, but, as a rule, it first appears in the earlier years of life. Dr. Wright's patient had had his lesions since infancy, the father's lesions had been present throughout life, and the daughter, who was 9 years of age, had had a typical lesion on her leg since infancy. Clinically porokeratosis is characterised by the occurrence of elevated wart-like lesions which, as they enlarge, form an irregular peripheral wall surrounding an atrophic depressed centre. The lesions show a distinct predilection for the hands and feet, genitals, buttocks, and scalp, although they may appear on any site. In a high percentage the mucous membranes are involved. The palms and soles almost invariably escape. Histologically the condition consists first in acanthosis and inflammatory changes in the corium, which are rapidly followed by hyperkeratosis with plugging of the sweat ducts and follicles. Except in the cases of individual lesions, which can be removed by excision or carbon dioxide, treatment is ineffectual. According to Dr. Wright porokeratosis is to be classified under the group of verrucose nævi, because of the wart-like condition of the lesions clinically, the epidermal hypertrophy as observed histologically, the familial tendency, the non-contagiousness, the persistence throughout life, the absence of inflammatory changes, the occasional systematic arrangement, and the failure to undergo involution as the result of X ray treatment.

YAWNING: ITS PHYSIOLOGY AND PSYCHOLOGY.

YAWNING is one of those curiously modified respiratory acts which has important physiological and psychological relations, not the least remarkable of the latter being what might almost be called its "infectious" nature, associated with imitation on the part of the beholder, and which in some people may be excited by thinking intensely of the act itself. C. Mayer in *Zeitschrift f. Biologie* (vol. lv., 1921) gives the results of his investigations in man by inspection, laryngoscopy, and X rays. The act itself he divides into three phases: 1. The initial phase, beginning with inspiration, widening of the chest, descent of the diaphragm and larynx until a certain depth of descent of both is reached, elevation of the wings of the nostrils, of the soft palate, drawing of the tongue upwards and backwards, dilatation of the rima glottidis. 2. The acme stage, full dilatation of the thorax to its greatest extent by means of the intercostal and accessory muscles, and descent of the diaphragm and larynx to their lowest position, accompanied by maximum depression of the lower jaw, further retraction of the tongue, and elevation of the soft palate. Tonic contraction of a varying number of individual muscles of the neck, shoulder, and region of the trunk. Wide lateral expansion of the mouth, closing of the eyelids, noise in the ears due to contraction of the tensor tympani, and a subjective feeling of pleasure and satisfaction. 3. Final phase, a short expiration, relaxation of the contracted muscles, ascent of the diaphragm and larynx, and elevation of the lower jaw, secretion of tears, and deglutition. The duration of the tonic contraction of the individual muscles is about 2·46 seconds, that of the whole inspiratory phase (phases 1 and 2) about 5·5 seconds. The biological significance of the acts seems to lie in the energetic ventilation of the lungs. The tonic phenomena accompanying the act can only in part be explained by the irradiation of the inspiratory impulses. This circumstance, along with the accompanying stretching of the arms and extension of the trunk, seem to indicate that the act of yawning and the participation therein of the pronounced contraction of certain muscles is of importance for aiding both the circulation and metabolism. The act itself would seem to be sub-cortical in origin, though it may be excited or discharged by psychical impulses. Spontaneous yawning is an expression of cerebral fatigue and the processes leading up to it stands in intimate relation to the function of sleep. If the optic thalamus is the part of the brain intimately concerned with sleep, then at a certain stage of fatigue the motor impulses for the act of yawning may proceed from it. In certain cases of encephalitis lethargica the execution of the act of yawning may be disturbed and modified.

A CLINIC FOR FUNCTIONAL NERVE CASES.

IT is generally recognised that progress in analytical psychology and experience gained during the war have together brought about notable advances in our methods of treatment. The Tavistock Clinic for Functional Nerve Cases was opened in September, 1920, in order to bring modern treatment for such conditions within reach of those who cannot afford specialists' fees, and to act as a centre for the study preventive surgery are found to be a plea for (1) measures that come under the heading of preventive medicine and education; (2) earlier diagnosis, and therefore earlier and more hopeful surgical treatment; (3) better surgery. The first is the ideal of the work before the Ministry of Health. Early diagnosis is a question already receiving earnest attention, and it is one of the main lines along which surgical advance is to be looked for in the future. With earlier diagnosis will come better operative results, as has already happened in cancer of the stomach, and often the avoidance of an operation. On the third count Mr. TURNER points the way to improvement. He speaks of the prevention of deformities which occur after fractures; but surely the treatment of a fracture so that deformity does not result is not preventive surgery but good surgery. So, to quote another instance, is the splinting of an ankylosing joint so that the resulting position of fixation shall be that most useful to the patient. That faulty ankyloses and malunited fractures are of lamentably frequent occurrence is a criticism which surgery has deserved. There are too many surgeons whose interest in the patient begins with the first incision and ends with the last safety-pin.

---

[1] Archives of Dermatology and Syphilology, October, 1921.

It is, however, becoming more and more evident that the operation is, in most cases, but one step in the treatment, and not a magic intervention, a wave of the wand which shall make the patient live happily ever after. This sounder, if less dramatic, outlook on surgery finds its expression nowhere better than in the repair of the injuries and deformities left by the war. It has been proved in many a military orthopædic hospital that the surgeon who gets the best results is not the brilliant operator, but the patient worker. A nerve suture is not merely a piece of deft needlework; its success depends upon a study of the man as well as of the lesion, a planning of the details long before the date of operation is fixed, a patient careful re-education of muscles and morale carried on for months afterwards. Still more does this apply to bone-grafting, where the most skilful carpentry will end in failure unless preceded by the correction of deformities and ankyloses, the excision of devitalised tissues, and the establishment of nutrition in the limb, to be followed by a carefully graduated resumption of function, which is the only call to consolidation to which the new bone will respond. These things are tedious, but they are as important as the operation, and they cannot be left to subordinates. The call for preventive surgery will result largely in the application of more of the surgeon's time to the essential if less dramatic details of his work.

◆

L.C.C. AND CARE OF THE BLIND.

THE Ministry of Health has approved the essentials of the scheme prepared by the London County Council for the welfare of blind persons in the County of London, particulars of which appeared in THE LANCET of August 6th. The Minister has expressed special satisfaction that a Central Council is to be established, and suggests that in carrying out the scheme every effort should be made to encourage the voluntary side of the work. The London County Council has appointed a Special Committee to administer the scheme, which will operate from Nov. 1st. Since the Central Council will consist principally of representatives of societies and associations dealing with the blind and persons with special knowledge of the needs of the blind, it has been decided not to appoint coöpted members on the County Council Special Committee.

Annotations.

"Ne quid nimis."

VENEREAL DISEASES IN U.S.A.

THE weekly report of the United States Public Health Service, dated Sept. 2nd, contains a summary of the work carried out in coöperation with the various State boards of health in combating venereal diseases during the past two years. The summary is divided into sections dealing with medical, educational, and legal measures, and with comparative activities in various States. Amongst the medical measures recorded are the following: establishment of 427 venereal disease clinics; the giving of 2,103,000 treatments to 185,200 clinic patients (at a cost of less than $1 per person in the most efficient clinics); discharge of 41,100 patients as non-infectious; following up by social workers of patients who cease attendance before cure, and of patients' families; the obtaining of the coöperation of 28,000 druggists in checking sale of patent remedies, and of a pledge of coöperation from 60,700 physicians. It is also noted that 15,000 placards have been posted; that of 20,000 newspapers and magazines all but 200 have agreed to remove or refuse advertisements of quack doctors; and that in 16 States it is unlawful to sell patent remedies. The same mass action is apparent on the educational side; 740,000 young men and boys have seen the "Keeping Fit Exhibit," 13,000 lantern lectures have been delivered, 3600 kinema shows have reached audiences totalling near 1½ millions of people; and so on. Conferences of teachers, distribution of literature, special lectures to coloured people have all been directed to the one end; moreover, legislation has been kept abreast of the spread of public enlightenment. Many houses of prostitution have been closed, and men found in such houses are now prosecuted equally with women. Three hundred and fifty ordinances dealing with the control of venereal diseases have been passed, and several States now have quarantine houses in which to harbour persons whose disease constitutes a danger to the public health. Institutions for the care of the feeble-minded are receiving particular attention, and much money is being spent to enable them to take care of persons who, if not under proper control, would be the means of spreading infection. The number of social workers employed is growing, and an increasing intelligence and efficiency is demonstrated in the handling of women suffering from venereal disease. Such well-directed and widespread effort cannot fail to have a very marked effect upon conditions of public health in the United States.

STUDY OF EMBRYOLOGY BY MODELS.

To the student the study of embryology is too often a matter for despair, since the only satisfactory way of getting a grasp of it is by practical work with embryological material. This entails not only a larger supply of embryos than it is possible under present conditions to obtain, but also a considerable amount of technical knowledge and skill, and more of the teacher's time than can usually be spared. The difficulty has even led to the pessimistic suggestion that this subject be excluded from the syllabus of medical examinations. There is, however, a possible solution—the use of accurate reconstruction models of whole embryos and their constituent organs. These, though occasionally seen on shelves in museums, are seldom used, and far too much reliance is placed on pictures, which however realistic, can never give as good an idea of structure as a model. An interesting series of models shown by Miss I. C. Mann at the meeting of the Section of Ophthalmology of the Royal Society of Medicine on Oct. 14th represented stages in the development of the human eye; they were pH nomenclature is almost universally employed at the present time for designating hydrogen-ion concentrations: it must, however, be constantly borne in mind that when the hydrogen-ion concentration of a solution—that is to say, its acidity—is increased its pH number is diminished, and vice versa; all solutions on the acid side of neutrality have a pH smaller than 7 and all alkaline solutions have a pH greater than 7. It must also be remembered that pH numbers are in reality logarithms, so that a given difference in the pH of two solutions does not represent any actual difference but only a proportional difference between their hydrogen-ion concentrations; thus the difference in hydrogen-ion concentration between pH 6·0 and 6·3 is 100 times greater than the difference between 8·0 and 8·3, though in both cases the second value is half the first (1/1,000,000; 1/2,000,000 and 1/100,000,000; 1/200,000,000 g. per litre respectively). Provided these peculiarities are borne in mind, the pH nomenclature can easily be employed by anyone without any knowledge of logarithms, and the determination of pH can be readily made by methods which are soundly based on theory, are of easy application, and require no special calculation.

Methods of Determination of pH.

The simplest of these methods is the indicator method; according to recent work it is more accurate where body fluids are concerned than more elaborate methods. It depends on the principle that certain indicators, such as neutral red or phenolsulphonephthalein, show a progressive change in colour as the pH of a solution containing them is altered, each tint being associated with a particular reaction. As it is quite easy to prepare standard solutions of known pH, all that is necessary is to find which of these standards gives the same tint as the unknown solution, when equal amounts of the indicator are added to each—in practice this is a very simple matter which need not be described in detail here. When, as with blood, the original solution is coloured, the method is slightly modified by dialysing the blood and finding the reaction of the colourless dialysate: provided that precautions are taken to prevent loss of carbon dioxide in the course of the dialysis, the dialysate has the same reaction as the blood from which it is derived, because it merely represents a diluted protein-free plasma, and it can be shown that neither moderate dilution nor removal of proteins alters the reaction of blood plasma. The exclusion of the corpuscles also has no influence, because by the reaction of blood we mean the reaction of the plasma alone: if no carbon dioxide is removed the reactions of whole blood and of the "true plasma" drawn from that blood are the same.

It would perhaps seem at first sight to be much simpler to titrate the plasma or its dialysate to a definite end-point with some chosen indicator and a standard acid and have done with the matter: to determine its alkalinity in other words. Such a procedure gives valuable information, it is true, but it tells nothing at all about the reaction of the blood; the same is true of determinations of the "alkali reserve." Both of these determinations give the bicarbonate content of the plasma, but the reaction of the plasma depends not on this alone, but also on the carbon dioxide pressure of the blood; it is, in fact, determined by the ratio between the two, the hydrogen-ion concentration varying directly as the ratio $\frac{CO_2}{NaHCO_3}$ and the pH varying as the logarithm of the ratio $\frac{NaHCO_3}{CO_2}$. The bicarbonate content of plasma may be reduced to half the normal amount, but if the carbon dioxide pressure is also half the normal, the reaction of the blood will be normal. Determination of the CO_2 of the alveolar air gives (in normal individuals at all events) some measure of the CO_2 pressure of the blood, and this, together with a knowledge of the alkali reserve, does enable us to arrive at some idea of the reaction of the blood: direct determination of the pH must, however, be regarded as far more satisfactory, and now that the technique of arterial puncture has been worked out there is no reason why it should not be made.

Buffer Substances.

The reaction of normal arterial blood is about pH 7·6, and this reaction is pretty steadily maintained under very varying conditions, owing to the presence of buffers in the blood. Buffers are substances which absorb acids without much alteration of reaction; this influence of buffers in "mopping up" acids is well seen in the case of blood plasma. Suppose one takes 10 c.cm. of blood plasma, and a similar amount of very dilute caustic soda solution of the same pH as the plasma, and adds to each solution 1 c.cm. of 1/100th normal hydrochloric acid, and, after well shaking, compares their reaction by means of indicators. It will be found that while the blood plasma has altered very little in reaction, the reaction of the soda solution has been changed to about pH 3. The principal or primary buffer of the blood plasma is its sodium bicarbonate, but whole blood is much more highly buffered even than separated plasma because, under all circumstances which tend to render the blood more acid, the corpuscles effect a counteracting change in the plasma by causing its bicarbonate content to be raised (secondary buffering); conversely, any change tending towards a more alkaline plasma leads to a reduction of its bicarbonate content by the agency of the corpuscles. We can conveniently regard the corpuscles as adding or abstracting bicarbonate to and from the plasma, though what actually happens is more complicated than that. The consequence of this action of the corpuscles is that whole blood has a most remarkable buffering power, towards both acids and alkalies; this secondary buffering of the plasma brought about by the agency of the corpuscles can best be judged from some actual figures, obtained from blood *in vitro*; when blood was exposed to air containing 0·13 per cent. of CO_2, the plasma contained 0·151 per cent. of $NaHCO_3$, and when saturated with air containing 12·5 per cent. CO_2 the bicarbonate of the plasma rose to 0·32 per cent.

The lower the corpuscular content of blood the smaller is the influence of this secondary buffering; anæmic blood, then, has a much smaller range of secondary buffering than normal blood; as a partial compensation for this the primary buffering of the plasma is not infrequently raised in secondary anæmias. It is more probable that the breathlessness of anæmic subjects is due to the less perfect buffering of their blood than to deficient oxygen supply, and, except in extreme cases, this applies to other states in which "air-hunger" occurs. But if in addition the oxygen supply is deficient, the condition becomes very much worse, because large amounts of fixed acids will then be thrown into the blood by the partially asphyxiated tissues, the plasma bicarbonate will be partially neutralised, and any compensation by increase of the primary buffering will thus be lost.

"Acidosis."

A little reflection on the mode of regulation of the reaction of the blood suffices to reveal a difficulty which is becoming daily more apparent; lowered bicarbonate content of the plasma by itself, or lowered alveolar carbon dioxide by itself, gives no information at all regarding the reaction of the blood; yet these are often accepted as evidence for the existence of a state called "acidosis." Nor does the plea that the term "acidosis" is justified in these cases on the ground that there is evidence that fixed acids have been formed and that these have neutralised part of the bicarbonate, carry any weight, because an increased excretion of alkali by the kidneys would also lead to a reduction in the plasma bicarbonate. A more acid state of the blood can only be inferred from such observations when we know both the carbon dioxide pressure and the bicarbonate content of the arterial blood, and the former can only be obtained from alveolar air analyses when it is changes have taken place in the pedicle that only special precautions will enable the surgeon to avoid the danger. Such changes are prolonged suppuration in or around the kidney, and carcinomatous infiltration of the pedicle, with subsequent matting of all the structures in the neighbourhood. Such cases may be dealt with in one of three ways, viz. :—

1. Ligature of each vessel individually.
2. Subcapsular nephrectomy with control of the renal vessels by the fingers until complete removal of the kidney, when the vessels can be readily caught and tied.
3. Transperitoneal nephrectomy, especially when dealing with malignant tumours.

The question arises of the treatment of those cases of duodenal injury in which the resulting duodenal fistula will inevitably cause the death of the patient if not treated. Jejunostomy is of no value, because the loss of bile and pancreatic secretion still continues and the inanition progresses. The fistula must be exposed and closed. Payr successfully dealt with his case by a three-tier suture, but McGuire Stuart maintains that a direct suture is rarely successful, and advocates Mayo's method. The duodenum is mobilised by incising the peritoneum along its right border, and then rotated forwards and inwards to give a full exposure of the wound in its posterior surface. The defect is closed by several layers of sutures, and afterwards covered by peritoneum. At the same time a temporary jejunostomy is performed for feeding.

CORRECTION OF ASTIGMATISM.

A CORRESPONDENT suffering from headaches which get worse on using his eyes writes to THE LANCET to complain that although he has consulted several oculists, and they have all given him nearly identical prescriptions to correct his astigmatism, his headaches remain unrelieved. The causes for this unfortunate result may be various. In the first place, his headaches may not be truly ocular at all, but dependent on the vascular system, and made worse by the stooping of the head usual in reading. In the second place, the astigmatism may be irregular, the result of a corneal scar, and therefore incapable of being wholly corrected by glasses. Thirdly, a fully correcting spectacle-lens accurately centred neutralises an error of refraction only when the line of vision passes through its optical centre. When, however, the line of vision is excentric (as, for instance, in reading a line of print without moving the whole head) the error will be over-corrected, and in the case of a strong lens considerably over-corrected, a fresh element of astigmatism being introduced. Hence patients whose error of refraction is high, whether astigmatic or not, usually find a full correction less satisfactory than a partial one. It must be noted, however, that this difficulty can be got over to a great extent by the device of periscopic lenses—i.e., concavo-convex—with the concave surface next the eye. In the fourth place full correction of refractive errors may throw extra work on the extra-ocular muscles in the effort to maintain binocular vision. Cases of high oblique astigmatism sometimes illustrate this. The oblique muscles, one of whose functions it is to maintain parallelism of the visual axes during vertical movements, resent having to do their work under totally new conditions, so that in prescribing glasses it may be necessary to compromise in the matter of the obliquity of the axes of the cylinders prescribed. Far more commonly the difficulty experienced by the extra-ocular muscles is due to an inequality in the refraction of the two eyes. When this is present an unequal prismatic effect is produced by directing the line of vision in any direction except through the optical centre of the two lenses, the inequality of the prisms being greater in proportion to the inequality of the lenses. This throws unequal work on the muscles, and in the case of the vertically moving muscles, work which they are very likely incapable of performing except at the cost of a great nervous strain. Hence the glasses which might cure a headache due to astigmatism might cause another headache due to hyperphoria. The remedy, of course, is to be found in compromise—a partial instead of a complete optical correction, but in extreme cases it may be necessary to abandon any attempt to secure binocular vision.

TIMES AND SEASONS.

THE third verse of the nineteenth Psalm, in the Prayer Book version, runs as follows: "There is neither speech nor language, but their voices are heard among them," and the Septuagint version says: "There are no speeches or words in which their voices are not heard." And the meaning of the passage is that although there be no audible speech among the stars, yet their language is intelligible to all nations. "In the stars," says a noted sixteenth-century preacher, "the countryman finds instruction for the times of his labour, the seaman for his navigation, the mathematician for his observation. So that the husbandman and the sailor who cannot read can yet understand the stars, and the philosopher who has read every book that was ever written cannot fathom their meaning." In a review of the volume of Annals of Medical History, which appeared in THE LANCET for Oct. 8th, it was noted that the diagram in the Handbook of Byrhtferd contained two circles showing the relations of the month to the movements of the moon. This calendar, as Dr. C. Singer points out, was evolved about A.D. 525, and is the Dionysian cycle in which the months consisted of 29 and 30 days alternately, an intercalary month of 30 days being inserted seven times in 19 years. Although, as Dr. Singer says, this calendar "has no practical value except for the calculation of Easter," he is not quite correct, except as regards Westerns, for the same, or essentially the same, calendar is used to-day by Mohammedan nations as a religious calendar. The month begins at sunset of the day when the new moon is first seen after sunset. Every odd month has 30 days, every even one 29, except in leap years, when the last month also has 30. It is not a convenient calendar, for every month retrogrades through all the different seasons of the solar year in a period of about 33½ years owing to the difference between the lunar and the solar year of about 11 days. Thus in the year 1880 the month Moharrem began on Dec. 4th; in 1890 it began on August 17th, and by 1912 it had got back again to Dec. 11th; but it is a matter of interest to all subjects of the British Empire that a sixth-century calendar should still be in use among the people of a large part of that Empire.

PARATYPHOID FEVER CAUSED BY "HEAD-CHEESE."

THIS outbreak of paratyphoid fever[1] in November, 1920, in a small American town is of considerable interest from a number of points of view. The cases were at first thought to be influenza with sudden onset, headache, chills, pains in joints, and rapid rise of temperature from 102° to 104° F. There were no pulmonary symptoms, and later clinical and bacteriological evidence showed that the condition was paratyphoid fever. Prolonged high temperature, papular eruption, and other symptoms of paratyphoid fever were present. Bacteriologically the diagnosis was confirmed by the isolation of *B. paratyphosus B* from the blood of two of the cases, from the stools of three cases, and by a well-marked positive agglutination reaction exhibited by the serum of 19 out of 20 cases examined. The incubation period was from 2 to 13 days, with an average of approximately seven days. The epidemiological investigation elicited the fact that the persons attacked were from homes widely distributed throughout the town, and were of various ages, from 5 months to over 50 years. Thirty-three of the 44 cases developed the country is compelled to work until his sixty-fifth year has given a great deal of trouble to medical men, who find themselves expected to estimate the working capacity of thousands of would-be idlers. Moreover, the stringent sumptuary laws include such provisions as the following: payment of a tax of 200 leva by anyone, irrespective of age or sex, who wears gloves between April 15th and Sept. 16th without a medical certificate to prove that the gloves are *indispensable for purposes of health*; payment of a tax of 100 leva by anyone of less than 50 years of age who carries a walking-stick without a medical certificate entitling him to do so. Bulgarian doctors now make out more certificates in a week than they have hitherto been used to making out in two or three years, and are apparently well paid for so doing.

[1] Paratyphoid Fever. Report of an Outbreak in Cascade, Mont., caused by Head-Cheese. *Public Health Reports.* Washington: Treasury Department. 1921. xxxvi., No. 35.

A "Dental" Swindle.

An original form of swindle was recently perpetrated by a youth who opened a "dental surgery" at Temesvar, and by advertising a scale of charges half that of any other dentist in the town, drew large crowds to his waiting room. He examined each patient, and if the person had gold crowns or stoppings he removed the latter, describing them as badly-fitting and in need of replacement. He then took a wax model and ordered the patient to return in a fortnight's time. In a fortnight he collected about half a kilogramme of gold with which he attempted to leave the country. He was arrested in the train, however, and brought back to Temesvar. Here it was ascertained that he was in reality a grocer's clerk, who had learned sufficient dentistry from a friend, a dentist's assistant, to enable him to put his fraud into operation.

Village Riot on a Doctor's Behalf.

In a Hungarian village the head of the registry office complained to a detective that in six months only one birth occurred in the village, where in former years the birth-rate varied between 65 and 80 yearly. The detective set to work, with the result that the village doctor, Dr. N. Somogyi, was taken in custody on the charge of having induced abortion in several hundreds of cases. Thereupon the village people, with whom the doctor was very popular, rioted and demanded his immediate release. However, on searching his house, the police found a long list containing the names of hundreds of women, and the fees they paid. The list contained among many modest sums some very considerable amounts—items of from 3000 to 10,000 crowns. An investigation was then opened amongst the women too, and it was found that some of them had burned fœtuses in a bread-baking oven. The investigation also made it plain that many husbands knew of the abortions. Dr. Somogyi defended himself by saying that he did not induce abortion, but only helped to finish the abortions already commenced. He wanted to pay into court 100,000 crowns security to be set free until his trial, but the jury refused to comply with his request.

Prosecution of a Charlatan.

An interesting judgment was recently delivered against a quack in a Hungarian court of law. A patient, advised by his medical man to have an operation performed for extensive hæmorrhoids, thought fit to consult a well-known unqualified "doctor," who gave an opinion contrary to that of the surgeon, and supplied some ointment and lotion, with the result that gangrene and proctitis set in; the patient returned to the surgeon, who performed the operation. The after-treatment lasted over three months, during which time the patient's life was endangered by the threat of sepsis. The patient sued the charlatan for damages and also tried to recover the fees he had paid. He did not get his money, and the judge, in sentencing the defendant to six weeks' imprisonment, made it plain that the punishment was not for quackery, but for preventing the complainant from following sound

CANADA.

(FROM OUR OWN CORRESPONDENT.)

University of Toronto.

THE Medical School has limited registration this fall to 110 persons, one-half the total number of applications, on account of lack of facilities for handling them. These, with the students who are repeating the first year on probation, comprise the first year in medicine. Selection of the successful candidates was made on the basis that first preference should be given to returned soldiers with the necessary qualifications; students who had obtained standing of a higher grade than junior matriculation were in the next group, and the third group consisted of students with junior matriculation over 19 years of age. Applications were restricted to the province. This decision to restrict registration was forced upon the authorities by reason of the increase of medical students. The present register contains 1106 names, while in 1918 it contained only 656. This university's registration in this department is the largest on the continent.

Ontario Medical Association.

A district meeting of the Ontario Medical Association was recently held at Peterboro', Ont., at which Dr. T. C. Routley, the secretary, gave an address on "Organisation Progress in Ontario and Other Provinces." He recapitulated the work of the Association and laid particular emphasis upon the need for proper standardisation of drugs and the necessity of informing the public as to what constituted competency on the part of all who undertook to treat the sick. The meeting was attended by many practitioners of Peterboro', Victoria, Durham, Northumberland, Hastings, Prince Edward and Haliburton counties. Interesting papers were presented during the afternoon session and prompted fruitful discussions. At the evening session Dr. F. W. Marlow, of Toronto, gave an address on "Symptomatology and Treatment of Some Gynæcological Conditions."

Drugless Healing and Chiropractic Bills in British Columbia.

A legislative committee was recently appointed to collect evidence for and against the Drugless Healing and Chiropractic Bills and has recently issued a report. The committee states that the question it had to decide was whether the chiropractors and the drugless healers had made out a case for an alteration of the present law, so that they might be permitted to practise the art of healing without hindrance. After receiving evidence from many prominent chiropractors, the committee recommended these should be allowed to continue their practice, but that suitable examinations should be set by the Medical Council, in order to secure competency on the part of chiropractors, &c., before they were allowed to establish a practice. The committee also suggested that the Medical Act be amended to include these provisions.

A New Tuberculosis Examiner.

Dr. T. M. Sieniewicz, of Halifax, Nova Scotia, for three and a half years associated with Dr. A. F. Miller in the Tuberculosis Sanatorium in Kentville, N.S., has been appointed to the position of Tuberculosis Examiner in the Massachusetts-Halifax Health Commission. Dr. Sieniewicz succeeds Dr. D. A. Craig, the first to hold this position. All of his time will be given to the Public Health work of the Commission, and to consultation work with physicians of Halifax and Dartmouth.

Hospital News.

A by-law is to be submitted to the electors of St. Thomas, Ont., authorising an issue of $100,000 in debentures for the erection of the proposed memorial hospital in connexion with the Amasa Wood Hospital. An expenditure of $160,000 is estimated for, $60,000 of which is to be raised by private subscription. It is proposed to erect a

X

and practice of psychotherapy. The methods employed include persuasion, suggestion, re-education, and various forms of analysis; no attempt is made to secure uniformity of method, since members of the staff may belong to different schools of thought, and, moreover, no rules can be made in the treatment of nerve cases. The aim in all cases is to restore the patient to social efficiency as quickly and as permanently as possible. Patients bringing a letter from their own doctor require no other recommendation, and pay if they can afford to do so. 219 patients have been treated during the year, involving 1784 interviews, lasting an average time of 50 minutes. Most of the cases treated in the children's department have been delinquents, chiefly thieving, and the results are said to have been uniformly good. Treatment has also been given for nocturnal enuresis and other disorders. Lectures and demonstrations are held for practitioners and medical students. A course on elementary psychotherapy is now being given by Dr. H. Crichton Miller, and during the coming year courses will be given by Dr. C. P. Symonds, Dr. J. A. Hadfield, Dr. E. W. N. Hobhouse, and Dr. W. A. Potts, who is the director of the children's department. Particulars of these courses may be obtained from the Hon. Lecture Secretary at the Clinic, 51, Tavistock-square, London, W.C. 1. While patients' fees and lecture fees go some way towards meeting the current expenses of the clinic, they are not sufficient to make it self-supporting, and help is urgently needed to enable the work to be carried on and extended.

CHEMICAL DISINFECTION AND STERILISATION.

IN a recent publication [1] Dr. S. Rideal and his son consider not only the various chemicals used as disinfectants and sterilisers, but also the details of their practical use, with some account of the experiments performed in connexion with their testing. A clear summary of the theory and technique of disinfection and sterilisation by chemical means will be welcomed by members of the medical profession as well as by numerous scientific workers.

Chemicals such as sulphur, copper, nitre, and numerous aromatic substances have been used from early times, but the number of suitable substances is now so large that a choice between them must sometimes be difficult. Moreover, the quantities of the steriliser to be employed, their times of action, as well as the best forms of apparatus for their production are of the utmost importance. Selection must depend largely on the nature of the object to be treated. Air may be sterilised by formaldehyde, sulphur dioxide, chlorine, and ozone. Chlorine is seldom used; formaldehyde and sulphur dioxide are mainly used for rooms, whilst ozone is suitable for large spaces. Chemicals used for food preservation must be chosen so as not to be injurious to health on consumption. There is thus only a limited choice, which is confined to those required for salting and smoking. Food in general is most commonly preserved by cold storage, milk by condensation and heat sterilisation. Water sterilisation is effected by filtration and sedimentation; ozone is sometimes used, but most frequently lime. Halogens as such or in the form of hypochlorites are also largely used. The destruction of non-bacterial parasites, such as insects, is another special problem; it is only successful when we know the life-history of the insect and is generally prophylactic in nature. The mode of action of the chemicals necessarily varies, being dependent not only on their own nature but on that of the object to be disinfected; physical processes such as ionisation, osmosis, surface tension play a large rôle. No specific action can be ascribed to chemical groupings in the molecule.

THE REACTION OF THE BLOOD:

THE MECHANISM OF ITS REGULATION.

BY C. A. LOVATT EVANS, D.SC.LOND., M.R.C.S.ENG.

THE questions of the reaction of the blood and the mechanism of its regulation have attracted the attention of laboratory investigators for several years past. Numerous definite results, some of which may prove to have a practical application to clinical problems, have accrued from this originally purely academic line of investigation. Their application is, however, largely a matter for future clinical investigation to reveal. It has long been known that blood, like most other tissues, normally has a slightly alkaline reaction, which it owes to the presence in it of sodium bicarbonate. Despite the fact that the circulating blood is the receptacle of very variable amounts both of acids and bases—waste products thrown into it by the active tissues of the body—its reaction is subject to surprisingly little variation in health or even in many pathological conditions. The liver and kidneys contribute a great deal to the regulation of the reaction of the blood, and the lungs, by removing carbon dioxide, constitute a valuable fine adjustment mechanism, but a still finer means of regulation than any of these resides in the blood itself. Blood is much more than a mere carrier of oxygen, food materials, and waste products; it is a valuable means of governing the reaction of all the other tissues in the body, the relation being mutual.

The Modern Meaning of "Reaction."

Let us first consider the modern meaning of reaction without looking too deeply into the physical chemistry of the matter. The theory of electrolytic dissociation teaches that water is to a very small extent decomposed into two ions, the hydrogen-ion (H) and the hydroxyl-ion (OH), the former bearing a positive and the latter an equal negative electric charge. Further, acids when dissolved in water add hydrogen-ions thereto, whereas bases by producing hydroxyl-ions lower the hydrogen-ion content. By the reaction of a fluid is meant the concentration of hydrogen-ions in it, and this can be expressed in terms of grammes of hydrogen present in the ionic state per litre of the fluid. Water itself, the standard of neutrality, contains 1 g. equivalent (i.e., 1 g.) of hydrogen-ion in 10 million litres; it is exactly neutral because it also contains in the same volume 1 g. equivalent of hydroxyl-ion. Water, then, may be regarded as either a 10-millionth normal acid or a 10-millionth normal alkali. All acid solutions contain more and all alkaline solutions contain less than 1 g. of hydrogen-ion in 10 million litres. The concentration of hydroxyl-ion is usually disregarded, because it always varies in the opposite way to the hydrogen-ion in such a manner that the product of the two concentrations is constant for all aqueous solutions whatsoever, neither ion ever quite vanishing. A simpler way of expressing hydrogen-ion concentration is to say that pure water has a H-ion concentration of 1/10,000,000 g., or more simply 10^{-7} g. per litre. Similarly a 1/1000 normal acid has a H-ion concentration of 1/1000 g. or 10^{-3} g. per litre; while a 1/1000 normal alkali has a hydrogen-ion concentration of 1/100,000,000,000 or 10^{-11} g. per litre. Since the expression 10^{-7} means 1 divided by 10^7 or 10,000,000 and 10^{-3} means 1 divided by 10^3 or 1000, this way of expressing fractions is very convenient; still more convenient for the expression of hydrogen-ion concentrations is the convention of omitting the 10 and the minus sign and prefixing the letters pH, writing pH 7·0, pH 3·0, and so on. The symbol "p" means "that power to which 10 must be raised to give the concentration in grammes of hydrogen-ion per litre" of the fluid in question. Since it is always negative for solutions weaker than N/1 acid, the negative sign is omitted by a convention. By a further convention, H in pH stands for the hydrogen-ion, and not the element, though usually the ion is designated by H^+, or more simply $H^\bullet$. This so-called the rate from other forms of tuberculosis 0·22. The increase in the tuberculosis death-rate during the war years was less marked than in many towns, but the decline in the rate since the war ended has been marked. A Bill is being promoted in Parliament for the purchase of the North Warwickshire Water Co. The sewage is dealth with partly on a sewage farm and partly by means of filter-beds, which are being extended. The treatment by activated sludge, which is proving so successful elsewhere, is not apparently being adopted for the extensions. The council have declared fried-fish shops an offensive trade, and have adopted the novel principle of hearing the opinion of the tenants within a radius of 100 feet before sanctioning the establishment of a fish shop. The principle seems a good one, but the distance of 100 feet does not err on the generous side. Dr. Snell gives figures showing that the community is becoming largely an unvaccinated one. A case of malignant pustule, traced to a shaving brush infected with anthrax, recovered. Of 160 deaths from tuberculosis, no less than 28 died unnotified. For the purpose of institutional and dispensary treatment the city is united with Warwickshire by a Local Government Board Order. An X ray apparatus has been installed at the dispensary since January, 1920, and has been used extensively for diagnostic purposes. Considerable attention is being given to the dental treatment of tuberculous patients. There were 280 new cases of venereal disease treated at the clinic; 49 cases ceased attendance before completing a course of treatment. One hundred and nine cases of suspected ophthalmia neonatorum were notified, the midwives being encouraged to notify the slightest discharge. Of these 105 are said to have made a total recovery; two died before recovery was complete, one infant is said to have had one eye permanently injured, and one to be totally blind in one eye. None of these cases were nursed in hospital. Dr. Snell submits a complete report as school medical officer. There are now two assistant school medical officers, two dentists, and five nurses. An interesting account is given of the work of Corley Camp residential open-air school, which has accommodation for 16 children. An open-air day school for physically defective children is held on the flat roof of Centaur-road School, which is visited by the organiser of physical training to advise the teachers with regard to special exercises. Of 1935 children referred for dental treatment, 1129 accepted treatment.

SCHOOL MEDICAL SERVICE.

MANCHESTER.

Dr. A. Brown Ritchie, school medical officer of the city, has just issued the twelfth annual report, dealing with the year 1920. Besides the chief assistant medical officer, there is a staff of 15 medical officers, three specialist officers (anæsthetist, surgeon, and consulting oculist), all on part-time duty, five school dentists (two on part-time duty), and 48 school nurses. In addition there are two masseuses and two nurse-attendants, and one remedial gymnast for the Lancastrian Day School for Crippled Children. Even with this not inadequate staff it cannot be maintained that each child requiring special treatment could receive it. There are only four dental clinics, which deal with 20,000 children out of the school population of 123,000, and another school clinic is urgently needed. There are no open-air day schools, nor can the present arrangement for educating and treating mentally defectives, crippled children, and partially blind children be in any way considered adequate. But the benefits accruing from school medical work become more marked year by year. There were 128,180 examinations by medical men, including 40,997 during medical inspections of schools, 81,195 at school clinics, and 2088 examinations of mentally defectives and epileptics. The school dentists examined 19,669 children at school and treated 17,758 at school clinics. Nurses paid 15,647 visits to homes and schools, and there were 202,774 special inspections for verminous conditions. The Danish treatment of scabies and the preparation and composition of the ointment (Marcussen) used are fully described. There are four special schools for mentally defective children; 305 children certified as feeble-minded attended ordinary schools, and 154 more were not attending any school. Five courses were held during 1920 for stammerers. Each course was restricted to a class of 10, and the total number who attended courses during the year was 46. For the majority of the cases one complete course of six to seven weeks was found sufficient for a satisfactory result, but the children are encouraged to attend on Saturday mornings for some time after the course is finished. In 15 of the stammering children (13 boys and two girls) there was evidence of other members of the family having stammered, and in one of the three cases with defective articulation a similar condition was reported in a parent. In 15 cases the condition was reported to have existed from the commencement of speech, and in 23 it was of later development. Body spasms of greater or less degree accompanied the stammer in 17 boys and three girls. The association of the stammering with general nervousness or a marked neurotic condition was frequently noticed. The results may be classified as 19 very good, 18 satisfactory, 7 fair, and 1 poor. In the tonsil and adenoid clinic—which is provided with an anæsthetic room, an operating theatre, and a ward of six beds—there were 1157 examinations and 925 operations. On operating days the patients are brought to the clinic and put to bed for an hour or more beforehand, during which time an injection of atropine gr. 1/100 is given to eliminate salivation as far as possible. Dr. H. Herd adds to Dr. Ritchie's report some interesting observations on "intelligence tests" based on the Stanford revision of the Binet tests. The Stanford revision seems to be more applicable to English children than either the Binet or Goddard revision. It was noted from the use of such tests as "repetition of digits," the æsthetic test (comparison of ugly and pretty faces), drawing square and diamond from copy, "fingers on hand test," &c., that the growth of mental faculty is not steady from year to year. It has rapid and slow periods, just as physical growth has, and in addition to that different capacities do not grow together in anything like equal amounts in any given period. This irregularity is more noticeable among the defective than among the normal.

CARDIGANSHIRE.

In 1919 Dr. Meredith Davies outlined a scheme for the prevention and amelioration of disease in the children of Cardiganshire. It is unfortunate and disappointing that nothing further seems to have been done in this direction; indeed, the report for 1920 is depressing reading. Out of 2181 children submitted to routine inspection, 345 were found suffering from malnutrition, 320 from defective vision, 540 from nose and throat disease, 1831 from dental disease, 162 from suspected and eight from definite pulmonary tuberculosis, and 203 from deformities. No cases of ringworm of the head were found, and only three of body ringworm. Only 350 children were free from dental disease; of the remainder 31 were found on re-examination to have been treated. One hundred and fifty-three cases of visual defect, and 32 cases of nose and throat troubles were treated. In spite of the large amount of malnutrition, there is no provision for feeding children, although a complete scheme was drawn up by Dr. Davies. Examination of secondary school children is impossible owing to the shortage of staff. The report consists of a series of negations; the school medical officer gets no help from any voluntary agency; there are no minor ailment centres; no provision for dental treatment, or for tuberculosis, or for eye and ear disease has been made, but an arrangement has been come to with the infirmary at Aberystwyth for the treatment of enlarged tonsils and certain that there is complete equilibrium between the alveolar air and the arterial blood; this certainty is lacking in many pathological conditions. The deductions from this line of argument are important and inevitable. Firstly, that the nomenclature of the whole subject of acidosis presses for revision[1]; secondly, that alveolar air examinations are not above suspicion; and lastly, that direct determination is the only satisfactory way of finding the reaction of the blood. It may be that blood reaction will, after all, be shown to be of secondary importance—that the body can tolerate a greater variation of hydrogen-ion concentration than has been previously supposed; it may be found that the all-important factor is the bicarbonate content of the plasma, or it may be that the carbon dioxide pressure is of most consequence. But these questions can only be settled by clinical research in which all three factors—namely, the reaction, bicarbonate content, and carbon dioxide pressure of the blood are measured.

Revision of the Children Act, 1874.

THE provisions of the French Children Act, 1874, are specially designed to promote physical health of children and to reduce infantile mortality. Mr. P. Strauss, member of the French Senate, now proposes to amend and consolidate it. In Part III. of his Bill it is suggested that at the time of the notification of birth a special nursing and maintenance booklet should be provided for all children without exception. The following notes would be compulsory: (1) birth registration particulars; (2) feeding, in the case of breast-feeding not being possible, the mode of artificial feeding should be indicated; (3) periodical weight records, the periodicity being determined by a Public Health Act; (4) minutes of periodical medical examinations by family doctor, or by medical officers who act as medical inspectors under the present Children Act, who would visit free of charge the children of poor people; the results of examinations could also be recorded by the medical officers of various charitable medical institutions; (5) vaccination. At the end of the month following birth, the book would be handed over to the local authorities, and again every three months during the first year and twice a year during the second year. Each time the book would be produced a visa would be apposed. If at any time the reading of the book shows that the child has not been under the regular medical attendance of a family doctor or under the supervision of a public or private institution, the local authorities will report the fact to the county medical inspector whose duty it will be to have the child medically examined. In the case of a second offence, the county medical inspector, after referring the fact to a special local commission, will have the privilege to have the child admitted to any special institution for the protection of infants. In the event of the parents protesting against such a decision, the county council authorities will enact without appeal, acording to the results of the inquest of the justice of peace. This proposed amendment to the Children Act has aroused great interest in medical and political circles over here.

Mental Diseases and Syphilis.

The Comité de la Propagande d'Hygiène et d'Education Prophylactique, with a view to publishing statistics of the connexion between syphilis and various psychoses as well as neuroses decidedly allied to general paralysis of the insane, proposes to open an investigation especially amongst medical officers in charge of asylums and physicians who are specialised is the study of mental diseases. The investigation is made from both a prophylactic and therapeutic point of view. Physicians will be asked to detail their observations as follows:—(1) Mental diseases caused by acquired syphilis: (*a*) mental conditions caused by syphilis alone and occurring together with other syphilitic stigmata; (*b*) mental diseases caused by syphilis and associated with psychopathic inheritance; (*c*) pathological findings in repeated lumbar punctures in cases of syphilis, and more especially in those complicated with tabes and encephalitis. 2. Mental disorders in cases of inherited syphilis, abnormal infancy, idiocy, epilepsy. 3. Frequency of mental disorders of syphilitic origin: (*a*) any personal statistics recording the frequency of mental disorders amongst syphilitics, as well as statistics giving the number of cases of mental disorders due to syphilis amongst any group of patients treated for all kinds of psychoses; (*b*) statistics showing the importance of the factor syphilis proportionally to the other causes of insanity (alcoholism, over-work, &c.); (*c*) the results of the routine use of the Wassermann reaction and of the cytological examination of the cerebro-spinal fluid of patients interned in various asylums. 4. Therapeutic results: statistics of results obtained by routine prolonged treatment with mercurial compounds and novarsenobenzol and similar drugs in various cases of mental disorders in which syphilis has been or has not been detected.

Paris Physicians and Surgeons at Strasbourg.

The fifteenth French Congress of Medicine, the thirtieth French Congress of Surgery, the twenty-first French Congress of Urology, and the third annual meeting of the Société Française d'Orthopédie were held at Strasbourg from Oct. 3rd to 8th. Amongst the congressists were some of the leading Paris physicians and surgeons. Prof. F. Widal, Mr. P. Abrami, and Mr. Pasteur Valery-Radot gave their views on anti-anaphylaxis; MM. L. Ambard and H. Chabanier reported on glycæmia; Mr. C. Lenormant, with Mr. H. Billet, described the results of the treatment of epilepsy consecutive to cranial traumatisms; MM. M. Chevassu and F. Rattery reported their views on anæsthesia in urinary surgery; Mr. L. Ombredanne reviewed various arthrodeses performed on the lower extremity.

(FROM OUR OWN CORRESPONDENT.)

Reform of Nutrition and Alcohol Consumption.

IN a recent lecture Dr. Dóczy, President of the Hungarian Order of Good Templars, said that according to his own experience and that of other investigators, the largely vegetable type of diet now customary in Hungary has lessened the desire for alcoholic drinks. The principles of modern nutrition, application of which resulted from the war scarcity of food, have great economic advantages; many people are both spending less on food and becoming capable of better work. The supplying of food to the army has also become much cheaper.

Infant Welfare in Budapest.

The Society for the Promotion of Infant Welfare has under consideration the adoption of the welfare scheme in force at Lübeck (Germany), the main provisions of which are as follows: *Care of children is a duty of the State; all illegitimate children must be brought up under medical supervision; infants' homes are placed in charge of Roman Catholic sisters; notification of births of illegitimate children is a duty of midwives, and the sisters thereupon call at the mother's dwelling.* When a birth is reported, pamphlets are issued to the mother, which contain information concerning the care of infants, together with a list of the infants' homes. The medical staffs of infants' homes are paid by the State.

Duties of Medical Men in Bulgaria.

For two years Bulgaria has been ruled by a peasant Government, and the new law by which everyone in

---

[1] The need for a revision was definitely expressed in the course of a discussion on Acidosis at the 1920 meeting of the B.M.A.

Hospitals, which had been 1896, 1969, and 1709 at the end of the three preceding months, rose to 2031 at the end of September; the weekly admissions averaged 322, against 235, 250, and 209 at the end of the three preceding months. Erysipelas was proportionally most prevalent in Paddington, Islington, Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. Of the 10 cases of poliomyelitis or polioencephalitis 2 belonged to Fulham. Five cases of encephalitis lethargica were notified during the month, against 10, 9, and 5 in the three preceding months. The notified cases of cerebro-spinal fever numbered 5, against 5, 7, and 0 in the three preceding months. The 23 cases of puerperal fever included 4 in Battersea, 3 in Fulham, and 2 each in Islington, Poplar, Southwark, and Lambeth. The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended Oct. 1st, the deaths of 3788 London residents were registered, equal to an annual rate of 10·9 per 1000; in the three preceding months the rates had been 9·4, 9·8, and 10·6 per 1000. The death-rates ranged from 7·3 in Hampstead and in Wandsworth, 8·9 in Greenwich, 9·7 in St. Pancras, 9·8 in Lewisham, and 9·9 in Woolwich, to 11·9 in Hackney, 12·0 in Stepney, 12·2 in Bethnal Green, 13·5 in Shoreditch, 13·7 in Finsbury, and 14·1 in Southwark. The 3788 deaths from all causes included 629 which were referred to the principal infectious diseases; of these, 7 deaths resulted from enteric fever, 3 from measles, 17 from scarlet fever, 50 from whooping-cough, 73 from diphtheria, and 479 from diarrhœa and enteritis among children under 2 years of age. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in St. Marylebone, Hampstead, Holborn, Wandsworth, Greenwich, and Lewisham; and the highest in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, and Bermondsey. The 7 fatal cases of enteric fever exceeded the average in the corresponding period of the five preceding years by 2. The 3 deaths from measles were 19 below the average; 2 of these deaths belonged to Poplar, and the remaining 1 to Bethnal Green. The 17 fatal cases of scarlet fever were 7 in excess of the average; of these, 2 belonged to Hackney. The 50 deaths from whooping-cough were 27 above the average; the greatest proportional mortality from this disease occurred in Paddington, Fulham, Stepney, Poplar, Southwark, and Deptford. The 73 fatal cases of diphtheria exceeded the average by 33; this disease was proportionally most fatal in St. Marylebone, Hampstead, Finsbury, the City of London, Poplar, Bermondsey, and Battersea. The deaths from infantile diarrhœa numbered 479, and exceeded the average by 171. This is the largest number of deaths from infantile diarrhœa recorded in London in September since the corresponding period of 1915, when they numbered 739; the greatest proportional mortality from this disease occurered in Kensington, Shoreditch, Bethnal Green, Stepney, and Southwark. The aggregate mortality in London during September from these principal infectious diseases was 51 per cent. above the average.

The deaths from influenza registered in London during the month numbered 21, against 30, 15, and 9 in the three preceding months, and an average of 23 in the corresponding period of the five preceding years.

Birmingham Cripples' Union New Convalescent School.—On Oct. 5th The Forelands, Bromsgrove, was formally opened by the Lord Mayor as a convalescent school for crippled children. A spacious mansion, beautifully situated, has been well adapted for accommodating 80 children. There are two open-air dormitories, with large schoolroom and dining-room, and every provision for open-air treatment. Education up to ordinary standards will be combined with gardening, manual instruction, poultry keeping, &c. This enterprise, made possible by an appeal through the *Birmingham Mail* which raised £15,000, marked the consummation of 25 years' work in *Birmingham on behalf of crippled children.* The Cripples' Union was founded to link up existing organisations, but it was soon found that these were inadequate and the Union itself undertook to make the necessary provision. There is now an admirable system of home visiting with an out-patient clinic, an organisation for "after-care" work, the Woodlands Surgical and Nursing Home, and finally the new convalescent school, a pioneer institution. In addition to the £15,000 a grant has been obtained from the Ministry of Health and the school was opened free from debt. Its maintenance will cost from £5000 to £7000 a year. Mr. Naughton Dunn and Mr. Wilson Stuart are to act as surgeons to the Union, and Dr. Rowlands, of Bromsgrove, will be visiting medical officer.

"Audi alteram partem."

THE REDUCTION OF THE CAPITATION FEE.

To the Editor of The Lancet.

Sir,—It is not without some feeling of shame that members of the medical profession will note on reading the report of the Minister of Health's reply to a deputation of the British Medical Association concerning the reduction of the panel capitation fee that he had occasion to remark, "I told you I was not going to haggle about this thing, and I am not." Well one may ask what provoked this retort, so little befitting negotiations between a Minister and a deputation of medical men, and the answer appears to be that the latter attempted by argument to save a few pence of the impending reduction.

Great publicity has been given to what is represented as the fighting attitude of the profession regarding this matter, and perhaps it is well that the view held by no inconsiderable section of the profession of medicine should be stated also. In his reply to the memorandum forwarded by the Federation of Medical and Allied Societies on Oct. 4th (published in your issue of Oct. 8th), the Minister states his appreciation of the grounds on which the Federation supports an inquiry into the National Health Insurance system and that he has under careful consideration the question of setting such an inquiry on foot. He states also that the financial condition of the country necessitates such reduction of the insurance practitioner's fee as is fair to both the country and the medical profession. He has announced now that the inquiry, originally asked for by the Federation in January, 1920, is going to be held, that it must cover all the ground and must be without prejudice.

Practitioners on the panel are informed that they are expected to share in the reduction of income that their non-panel colleagues and practically all other sections of the community have experienced already. Therefore it is interesting to estimate exactly what that reduction will be. Three examples will suffice:—

1. The doctor with 3000 panel patients accepting the reduction of 1s. 6*d*. per capita will lose £225 of the £1050 per annum he receives now. The B.M.A. attempts to save him £75 of this sum. 2. Recently a practice of £2400 including a panel of 1300 was advertised. Under the proposed reduction the value of this practice is reduced by £97 10s. The B.M.A. attempts to save the vendor £32 10s. of this. 3. The practitioner with a panel of 500 stands to lose £38 10s., of which sum the B.M.A. proposal would save him £12 10s.

All will sympathise with the men, and many there be, who have given of their best to the service regardless of remuneration and are likely to continued so to do. Others will find consolation in the fact that the present reduction is equivalent to less than half the increase awarded in March, 1920. But we believe that a majority in the profession are too proud of their calling and too jealous in their service to the community to condescend to "haggle over sixpence," and we believe these will agree that the only proper and dignified course to take lies in acceptance of the Minister's proposal as part of a necessary national economy shared by all.

At the same time it appears necessary to press for an early and independent inquiry into the working of the Acts to ascertain *not* what the profession is willing to give the people for 9s. 6*d*., but how far the system has tended to improve the nation's health and how a more fully efficient service can be provided, linked up with general practice and with specialised branches. No fee that the people of this country can afford would be too high for such a service and certainly they would not begrudge it.

We are, Sir, yours faithfully.

Malcolm Morris, Vice-President.
Chas. Buttar, Hon. Secretary.
N. Howard Mummery, General Secretary.

Federation of Medical and Allied Societies, 12, Stratford-place, W. 1, Oct. 17th, 1921.

new sanatorium on the site of the old Delmonte Hotel buildings on the top of the hill at Preston, Ont. When the new sanatorium is completed it is expected to eclipse any other in this country and to rival institutions at Clifton Springs and other famous United States health resorts. The new sanatorium will command a magnificent view of the town of Preston and the surrounding country. Recently at Oshawa, Ont., a campaign was launched to raise money for the National Sanatorium Million Dollar Fund. Many prominent representative men from this locality were present at the meeting, amongst whom were Dr. T. W. G. MacKay, of Oshawa, and Dr. Kendall, superintendent of the Muskoka Free Hospital.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

EDINBURGH.

THE estimated population for 1920 was 336,923; the birth-rate (corrected for country births), 23·1; the death-rate, 13·2; the infant mortality rate, 80; the phthisis death-rate, 0·84; and the total tuberculosis death-rate, 1·21. Dr. A. M. Williamson draws attention to unsatisfactory housing conditions, and to the facts that for some years only the "very minimum" of repairs has been done to the property occupied by the poorest section of the population, and that 37 per cent. of the population live in houses consisting of one or two rooms. Cancer caused more deaths than all forms of tuberculosis. The tuberculosis death-rate, 1·2, though not a low one, is the lowest on record for Edinburgh. The chart showing the decline in the phthisis death-rate since 1873 in Scotland and Edinburgh respectively is an interesting one. The decline in Edinburgh has not been retarded by the war, and has, in fact, been more rapid since the outbreak of war than previously, while the Scottish curve shows the effect of the war. Edinburgh certainly, and perhaps Scotland as a whole, fared better than most parts of England in the matter of food during the war years. Probably, too, there was less strenuous factory work in Edinburgh than in the south. The Glasgow small-pox outbreak gave a stimulus to vaccination in Edinburgh, and Dr. Williamson estimates that over 80,000 persons were successfully vaccinated or revaccinated. The occurrence of two cases of small-pox in Craiglockhart Poor House was alarming. About 900 inmates were vaccinated, and the outbreak was limited to six modified cases among the contacts. The maternity and child welfare scheme is a very comprehensive one, and includes ante-natal clinics, preventive and curative clinics, mostly held at the dispensaries, day nurseries, child gardens, and convalescent homes. Dr. Williamson considers that the lack of medical attendance at their homes for children who cannot be brought up to the centre is a weak point in the scheme. Sixty-six cases of ophthalmia neonatorum were notified. We learn that one case died in hospital, but that six others were discharged with the eyes in a satisfactory condition. (Information as to the extent of eye damage among the home-treated cases would have been of interest.) The venereal diseases scheme is far-reaching and satisfactory, and good work in the treatment of infected expectant mothers is being carried out at the Royal Maternity Hospital. Dr. Williamson is alive to the weak points in the scheme. The lowest class of sufferers, "who are utterly careless of themselves and of others," need not and do not attend the clinics. Again, in a very considerable number of cases the first visit to the clinic proves to be the last. Dr. D. Lees, the clinical V.D. medical officer, is emphatic that something must be done with regard to the 30 to 40 per cent. who fail to continue attendance for a sufficiently long period. The report of the veterinary inspector, Mr. Gofton, shows that there are about 1605 cows stalled in the city. Twenty-seven were removed from dairy byres during the year on account of tuberculosis. Of these 18 were affected with tuberculosis of the udder, 8 were the subjects of advanced clinical tuberculosis with emaciation, and the remaining one was eliminating tubercle bacilli in the milk. Mr. Gofton points out that since the local authority has no power to require slaughter in these cases, there is no guarantee that the milk of these cows is not used after they are turned out of the city byres. In nine cases the cow is known to have been slaughtered. Two large dairy herds are now free from tuberculosis, and others are in course of being cleared.

STOCKPORT.

The estimated population for 1920 was 130,635. The birth-rate, which was 13·84 in 1918 and 15·05 in 1919, rose in 1920 to 22·2. The death-rate was 12·87, the lowest ever recorded. The infant mortality rate was 97, and the death-rates from phthisis and other forms of tuberculosis were 0·94 and 0·24 respectively. Dr. H. E. Corbin tells us that both scarlet fever and diphtheria were epidemic in the town during the year, both in mild form. At the last census there were 5436 female cotton operatives, of whom 2236 were married, and 1584 females employed in the hat and cap trades, of whom 277 were married. The number of still-births known was 154—i.e., 5·3 per cent. of the live births. The infant mortality rate for legitimate children was 93, and for illegitimate children 188. There are still 1188 privy ashpits, with 2074 privies to be converted. The work of converting them has been resumed, 32 having been dealt with in 1919 and 328 in 1920. High prices have retarded progress. Under the heading "milk-supply," Dr. Corbin says: "A sterilised milk depôt was established in the town as a private undertaking during the year. This depôt has already a very large daily delivery of sterilised milk, either directly to the consumer or through the milk vendors. It is under the supervision of the local authority, and the samples which have been analysed, both chemically and bacteriologically, were found to be satisfactory." This development will be watched with interest. Dr. Corbin points out that only about half the children born are successfully vaccinated. Stockport showed no increase of tuberculosis during the war, perhaps because the women were already largely employed in the mills. At the beginning of the year a centre was opened at the borough dispensary for the free treatment of venereal diseases. Stockport patients also used the Manchester centres. The first municipal maternity and child welfare centre was opened in August, and a rota of voluntary workers, largely members of 60th Cheshire V.A.D., has been formed to assist in the work. Of 65 cases of ophthalmia neonatorum notified, 51 were treated successfully by the health visitors acting under the instructions of the medical attendant. Six cases had eventually to be sent to the Manchester Royal Eye Hospital. In how many cases ultimate damage to eyesight ensued is not recorded. By agreement with Hyde Corporation four beds are retained at the Hyde Small-pox Hospital for Stockport patients, so that in the event of an outbreak the first few cases could be treated without disturbance of the tuberculosis patients accommodated at the Stockport Small-pox Hospital.

COVENTRY.

The population of Coventry has increased very rapidly. In 1901 it was 70,300, and for 1920 the estimated population is 140,000. According to Dr. E. H. Snell, with the exception of sandblasting, none of the occupations followed can be described as specially injurious. The birth-rate for 1920 was 23·2, compared with 18·2 for 1919. The death-rate, 9·0, was the lowest on record. The infant mortality rate was 76. The phthisis death-rate was 0·91, and of school work for children. The present writer has always advocated the minimum of interference with the education of the child with cardiac disability[1]; in the recently published Encyclopædia of Education he has also indicated the rôles of education and games[2]; every effort should be made to keep the child from dwelling on his physical condition; such expressions as "weak heart," "heart disease," &c., should be avoided in his presence.

In the course of an extensive experience with heart cases in hospital and private practice the writer, in common with other physicians, has been able sufficiently to improve the condition of patients to allow them to return to their former employment; treatment and rest have not only restored a more normal function, but have also built up a certain amount of cardiac reserve. With the majority of these patients, however, this cardiac reserve is sooner or later exhausted, and the patient returns to hospital in a more advanced stage of disease. This sequence of events is repeated until the end is reached; it is in these cases that occupational therapy might at least have postponed the catastrophe. Temperament and adaptability must be made important factors in the selection of appropriate work. Two cases recently under the writer's care may be given in illustration.

A schoolboy, aged 15 years, was first seen in 1915 on his approaching entry into a public school. The question was the extent to which he should be allowed to play games. The boy was in good health, but examination revealed mitral stenosis; directions were sent to the house master, and the school doctor observed the effects of the games prescribed. Later I had a satisfactory report from school and parents. Four years later, without reference to my opinion, the lad was articled to a firm of engineers. All went on well until he passed into "the shops": after a while he had sudden severe cardiac pain followed by a fainting attack, which was the occasion for a further consultation. On examination the presystolic murmur was well in evidence, the cardiac dullness was markedly extended to the right, and the apex beat outside the nipple line; there was also epigastric pulsation. A period of complete rest followed by graduated exercises restored the heart to a fairly normal state. It was decided he should have a lighter job, and he obtained a post in which clerical work was associated with engineering experience. The result has so far been satisfactory.

A man, 56 years of age, had symptoms of angina pectoris. The history showed that as a boy his health was not good: as his intelligence was not of a high order his parents had failed to educate him. He had a marked talent for music, but this had not been cultivated.

With Dr. Brush's record of success in heart cases by means of occupational therapy before us, alongside our own experience in cases lacking that valuable adjunct to treatment, one cannot but hope that once the need for an institution such as the Burke Foundation is made known means will be provided for its establishment in this country.

I am, Sir, yours faithfully,
CHARLES W. CHAPMAN.
Harley-street, W., Oct. 14th, 1921.

DIAGNOSIS AND TREATMENT OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—Some years ago I pointed out in your columns that cases of scarlet fever recovered more slowly and less perfectly in the fever hospitals of London than similar cases treated at home. I could only ascribe this difference to the aggregation of cases in the hospitals, with consequent abundance or concentration of the poison. Probably the same is applicable to diphtheria even in a greater degree; this, being a zymotic disease with serious implication of the throat and air passages, requires dispersion of cases and abundance of fresh air and sunlight. I do not, however, think that any hospital conditions justify what seem to me the erroneous views of and dangerous advice given by Dr. F. H. Thomson in his article on this subject published in your issue of July 9th, p. 68. With his strong approval of antitoxin I am in accord, though I am inclined to think that many medical men find somewhat smaller doses, provided these are given early, to be sufficient. I am not aware, though, that larger doses are harmful. The fault that I find with Dr. Thomson is his advocacy of complete and prolonged recumbency in all cases—even if only mild or moderate in degree—as most of them are. In mild cases without much pyrexia, I do not see that absolute recumbency is necessary; and when pyrexia has subsided, it is not merely unnecessary but prejudicial. There seems to be prevalent an idea of "heart weakness," which in ordinary mild cases (and the exceptions I believe to be very few) I look on as purely imaginary. The special focus of trouble in all, and especially the laryngeal and tracheotomised cases, is the lungs, which are more or less filled with noxious mucus and secretions inhaled from the throat, and are apt to become collapsed and even *pneumonic. This is the chief cause of remaining* debility, including any disturbance of the heart. The lungs naturally get poisoned by the inspired air passing through the foul throat. The main object of treatment in hastening convalescence is to promote active respiration and get the lungs expanded in the purest air that can be got. This cannot be effected while the patient is lying passively in bed in a sick room; suitable activity—as much as can be borne—is required. I do not deny that there may be cases where the heart is peculiarly attacked, but these are very unusual and I have no experience of them. Those cases which are complicated by affection of the vagus nerve, when a serious condition sets in almost suddenly with vomiting and great and progressive slowing of the pulse, are, I believe, always fatal, whatever treatment is employed. I think that since the introduction of antitoxin they have become much less common. I do not remember having seen one since.

I will not prolong this letter by discussing the advisability of local treatment. The various methods are set out in the text-books, with various opinions as to their merits or the reverse. For my own part I am at one with Dr. Thomson in disapproving of all strong and irritating applications, whether used as "antiseptics" or not, though I think that it is always beneficial to keep the throat as clean and sweet as possible by the use of permanganate solution, as gargle or swab, which is quite harmless and painless.

I am, Sir, yours faithfully,
F. LUCAS BENHAM, M.D., M.R.C.P.
Exeter, South Australia, Sept. 3rd, 1921.

POLYPOID DECIDUAL ENDOMETRITIS.

To the Editor of THE LANCET.

SIR,—In your otherwise excellent report of the paper read before the Section of Obstetrics of the Royal Society of Medicine on the above subject, there is one obvious error, which, however, I point out to correct. The report says that the disease "might extend down to the external os." It should, of course, be *internal* os.

The only point that needs correction in the necessarily condensed summary of the discussion, is that I am credited with the statement that "I could not say what proportion of septic cases were *due to polypoid* decidual endometritis." I do not remember that this specific question was asked, but I do say that probably 50 per cent. of all septic cases will be found to be due to this condition, especially if the microscope be more generally employed in midwifery work.

Permit me to add that in some cases of polypoid decidual endometritis death is known to have occurred on the tenth day following delivery, so that the postponement of any operative measures till after that date cannot be recommended.

I am, Sir, yours faithfully,
FRANK A. NYULASY, M.D., B.S.
New Metropole Hotel, Northumberland-avenue,
Oct. 17th, 1921.

[1] Heart Disease in Childhood and Youth. Medical Publishing Company. 1900.

[2] "Heart Strain in Children from the School Clinic and Educational Point of View," an article in the Encyclopædia of Education. Sir Isaac Pitman and Co. 1920.

adenoids. One hundred and thirty children were found to be dull and backward, and for these also no provision has been made. An open-air school is greatly needed in the county. Dr. Davies finds that although school closure is of very little use in the prevention of infectious disease, the fact that teachers are paid according to the average attendance is an inducement to them to desire school closure. It is unfortunate that so much lethargy in regard to health matters prevails in the county, and that the school medical service is subjected to such severe restrictions.

Hyde.

Out of 2056 children examined, 1747 suffered from dental defects, 267 from non-tuberculous lung trouble, three from definite pulmonary tuberculosis, 348 from nose and throat diseases, including 87 cases of enlarged tonsils and adenoids. Dental treatment was received by 116 children, while 16 cases of nose and throat troubles were treated under the authority's new scheme. Of 1363 cases of minor ailments, which received treatment, the majority consisted of impetiginous and other skin affections. The clinic is open for two hours daily, excluding Saturdays, and Dr. C. S. Thomson has arranged for all children suffering from bronchial catarrh to be seen weekly. Where medicine is required the child is sent to the family doctor. Twenty per cent. of the children had dirty heads; this appears a high percentage, but it must be remembered that the same standard of cleanliness is not accepted by all authorities. If school nursing was thoroughly carried out the numbers could be reduced considerably. The report shows at least 50 children with crippling defects, and Dr. Thomson suggests the formation of a guild of help to deal with these cases. An earnest endeavour is being made to raise the hygienic standard in this borough.

VITAL STATISTICS OF LONDON

DURING SEPTEMBER, 1921.

In the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 14·0 per 1000 of the population, estimated at 4,531,971 persons in the middle of 1920; in the three preceding months the rates had been 9·4, 10·3, and 8·5 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Chelsea, St. Marylebone, Lambeth, Wandsworth, Deptford, and Lewisham; and the highest in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The prevalence of enteric fever was nearly a third greater than in the preceding month; of the 45 cases notified during the four weeks ended Oct. 1st, 8 cases belonged to Wandsworth, 6 to Poplar, 5 to St. Marylebone, 4 to Kensington, and 3 to Camberwell. There were 37 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 23, 27, and 32 at the end of the three preceding months; the weekly admissions averaged 7, against 4, 5, and 5 in the three preceding months. The prevalence of scarlet fever showed a marked increase over the previous month—76 per cent.—and was considerably higher than in any preceding month since November, 1920; this disease was proportionally most prevalent in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, Poplar, and Bermondsey. The Metropolitan Asylums Hospitals contained 4847 scarlet fever patients at the end of the month, against 3621, 3722, and 3408 at the end of the three preceding months; the weekly admissions averaged 840, against 506, 567, and 467 in the three preceding months. Diphtheria also was considerably more prevalent—53 per cent.—than in August, and was about equal to the average of the first three months of the year; the greatest proportional prevalence of this disease occurred in Hampstead, Hackney, Holborn, Shoreditch, Stepney, Bermondsey, and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING SEPTEMBER, 1921.

Medical News.

University of Cambridge.—At the Second Examination for Medical and Surgical Degrees held recently the following candidates were successful :—

Part II., Pharmacology and General Pathology.—F. N. Adams, C. Adamson, G. L. Alexander, R. D. Alexander, H. S. Allen, W. B. Arnold, H. F. Brewer, G. C. W. Brown, N. F. C. Burgess, B. H. Burns, J. T. Burrell, G. A. H. Buttle, R. T. Chadwick, H. D. Chalke, P. F. Chandler, B. H. Cole, H. V. Coverdale, D. Cuffey, W. I. Daggett, C. H. C. Dalton, W. Daniel, J. H. T. Davies, P. O. Davies, F. M. Deighton, G. W. S. de Jersey, W. F. Eberlie, A. B. Eddowes, A. Elliot-Smith, J. B. Ellison, R. B. Fawkes, C. W. S. Fernando, K. Fletcher-Barrett, J. H. Francis, J. H. Gaddum, J. A. Galletly, W. H. Gervis, N. T. Glynn, T. S. Goodwin, H. W. Gordon, F. E. Graham-Bonnalie, J. Gray, O. Gray, S. J. P. Gray, F. N. Green, H. L. H. H. Green, J. V. Griffiths, C. J. P. Grosvenor, C. C. Halliwell, A. C. Hampson, H. E. Harris, P. M. D'A. Hart, B. D. Hendy, R. A. Hickling, C. H. Hilliard, E. G. Holmes, J. Holmes, W. S. Hunt, W. E. Hunter, J. P. W. Jamie, J. W. W. Jepps, F. H. King, M. C. H. Kingdon, R. L. Lancaster, A. L. Lankester, F. W. Law, G. A. Q. Lennane, S. Levy-Simpson, W. A. Lister, R. J. Lythgoe, A. F. McGlashan, W. W. McLean, D. P. Marks, L. P. Marshall, G. A. Metcalfe, H. D. N. Miller, K. F. T. Mills, E. F. Molony, W. B. R. Monteith, A. C. Mowle, E. B. Murrell, *J. Ness-Walker, T. M. Preece,* L. W. Proger, R. J. V. Pulvertaft, W. Richards, J. A. W. Roberton, R. E. Robinson, R. A. M. Scott, J. W. Shackle, C. J. L. Sharp, F. A. H. Simmonds, A. J. Smyth, J. H. Smyth, H. L. Sparrow, J. D. M. Stewart, G. B. Tait, J. H. G. Thompson, K. H. Uttley, F. C. O. Valentine, W. J. Walters, Y.-S. Wan, E. R. Weaver-Adams, V. B. Wigglesworth, C. E. Woodrow, and H. Yates.

University of St. Andrews.—At the Third M.B., Ch.B. degree examination held recently the following passed in Pathology: Thomas Christie, Lewis Farrell, Lutfur Rehman Khan, Ena McAlistair Liddell, John Russell Murray, Noel Nelson, John Petrie, James Alexander Robb, and Donald Bruce Smith.

St. George's Hospital Medical School (University of London).—The following Entrance Scholarships and Exhibitions have been awarded :—

90 guinea scholarship: G. K. Thornton, Corpus Christi College, Cambridge; £70 scholarship: R. W. Smith, Downing College, Cambridge.

Exhibitions of the value of 40 guineas each: E. F. Johnson, King's College, London; A. J. Smyth, Emmanuel College, Cambridge; and H. R. Mathews, Corpus Christi College, Cambridge.

St. Thomas's Hospital Medical School.—The following entrance scholarships have been awarded for the sessions 1921–22 :—

Entrance Scholarship in Arts, £25: R. A. Hill, Merchant Taylors' School.

Entrance Scholarship in Natural Science, £150: J. M. Ashton, Intermediate School, Towyn and St. Thomas's.

Entrance University Scholarship, £100: divided between R. J. V. Pulvertaft, Trinity College, Cambridge, and C. A. Lupton, Trinity College, Cambridge, equal.

National Baby Week Council.—The annual general meeting of the Council will be held on Oct. 25th, in Armitage Hall, 224, Great Portland-street, W. (by permission of the National Institute for the Blind), at 3 p.m., under the presidency of Viscount Astor, chairman of the Council. The principal speaker will be Dr. W. Allen Daley, M.O.H. for Blackburn, whose subject will be the Economic Value of Maternity and Child Welfare Work. The address will be followed by a discussion. Tickets for the meeting may be obtained from the Secretary to the Council, at 5, Tavistock-square, London, W.C. 1.

Royal College of Surgeons of England.—A quarterly Council meeting was held on Oct. 13th, with Sir Anthony Bowlby in the chair.—The secretary reported the death of Mr. John Ward Cousins, past member of the Council, and deep regret and sincere sympathy with his widow and family was expressed by the Council.—It was announced that an agreement had been reached between the Council and the Secretary to the War Office with reference to the care of the Army Medical War Collection of Pathological Specimens by the College.—Mr. F. F. Burghard submitted a draft copy of the annual report of the Council which will be presented to the Fellows and Members at the annual meeting on Nov. 17th next. The report was approved and adopted.—A report was read from the committee of management recommending the recognition of the High School for Girls, Wimbledon, for instruction in chemistry, physics, and biology, and reporting that Sir William Hale-White and Mr. W. F. Haslam retire by rotation from the committee.—Mr. W. G. Spencer was elected a member of the committee of management.—The President reported that the portrait of the late Mr. Hugh Owen Thomas, of Liverpool, presented by Sir Robert Jones, had been received and had been hung in the inner entrance hall. The thanks of the Council were given to Sir Robert Jones for his gift.—A letter was read from the College of Preceptors stating that they are endeavouring to arrange for the formation of a joint committee representing the medical and teaching professions to inquire into the present practices in the physical training of girls and their effects, and asking the College to appoint two representatives to serve on the proposed committee. The Council nominated Sir Charles Ryall and Mr. W. G. Spencer to represent them on this committee.

Museum Demonstrations.—The following demonstrations of specimens in the Museum will be given in the Theatre of the College in Lincoln's Inn Fields during October and November at 5 p.m. The demonstrations are open to advanced students and medical practitioners. On Monday, Oct. 24th, Prof. S. G. Shattock will demonstrate on Papilloma and Adenoma, on Oct. 31st on Degenerations and Necrosis, and on Nov. 7th on Cysts. On Friday, Oct. 28th, Sir Arthur Keith will give a demonstration on Effects following Disordered Action of Thyroid, illustrated by lantern slides. On Nov. 4th he will show specimens and slides illustrating various kinds of disordered growth at the epiphyseal line, and on Nov. 11th he will demonstrate on recently added specimens of clinical and anatomical interest.

Chelsea Clinical Society: Annual Dinner.—This dinner will be held on Tuesday, Oct. 25th at the Café Royal, Regent-street, London, W., at 7.30 o'clock.

Old Students' Dinners.—*St. George's Hospital.*—The opening of the winter session at St. George's Hospital Medical School did not include the customary introductory address. More than 80 past and present pupils of the school were present at the annual dinner at the Imperial Restaurant, Regent-street, on Oct. 1st, under the chairmanship of Dr. H. A. Des Vœux. The Chairman, in proposing the toast of the evening, "The Corner," recalled his own experiences as a student some 40 years ago and contrasted the position of the school at that time with that of to-day. He made a sympathetic allusion to the death of Mr. Warrington Haward. This speech was responded to by Mr. E. B. Turner on behalf of the past students, who recalled the wonderful athletic prowess of the school in his day and urged St. George's to get back to this ideal as quickly as possible. The Dean spoke on behalf of the present students and intimated in his remarks that the entry this year was the best that has occurred for some years. Dr. T. Vincent Dickinson gave the health of the chairman and spoke of his great services to the community in his professional and public capacities as chairman of the Coal Smoke Abatement Society and as organiser of measures for the relief of our Belgian professional confrères and their dependents during the great war. This was received with muscial honours, and Dr. Des Vœux replied. Finally, Sir George Turner gave the health of the dinner secretaries, Mr. Claude Frankau and Dr. J. A. Torrens.

University College Hospital Medical School.—The annual dinner of past and present students was held at Oddenino's Imperial Restaurant on Oct. 6th. The chair was taken by Dr. Henry D. Waugh, and over a hundred old students attended. The toast of "The Hospital and Medical School" was proposed by the chairman and was responded to by the Dean, Dr. G. F. Blacker. A pleasant musical programme was supplied by Drs. Poynton, Leslie Williams, Somervell, and Claremont, and the evening concluded with the toast of "The Chairman," proposed by Sir Rickman Godlee.

Westminster Hospital.—The annual dinner of past and present students was held at the Great Central Hotel on Oct. 7th, Sir Charles Ryall, presiding. The attendance numbered 101, including seven ladies. Sir Charles Ryall proposed the toast of "The Hospital and Medical School," to which Dr. A. S. Woodwark, the Dean, replied, pointing out the successful development of the medical school on its return to pre-war conditions, the present number of students being the largest for the past 15 years. Mr. Arthur Evans proposed "The Past and Present Students," to which Surgeon Rear-Admiral W. E. Axford, Lieut.-Colonel A. de C. Scanlan, and Dr. Walter Barron replied, the latter expressing his pleasure as a general practitioner that the hospital was to remain in its present situation. Mr. Souttar also spoke on behalf of the present students and referred to the exceptional teaching facilities provided. Mr. Rock Carling proposed "The Visitors," for whom Sir Murdoch Macdonald, and Dr. Edwin Smith responded. Mr. W. G. Spencer proposed "The Chairman," who, in his reply, read out some of the testimonials he had received as a student, including those of Dr. F. de Havilland Hall, consulting physician to the hospital, and Mr. Spencer, both happily present on this occasion.

ANKLE-JOINT FRACTURES.

To the Editor of THE LANCET.

SIR,—Sir W. Arbuthnot Lane, in his instructive paper on Abduction Fractures of the Ankle-Joint in THE LANCET of Oct. 1st, has done well to draw the attention of surgeons both to the mechanics of the injury, as well as to the permanent lameness which only too frequently is left behind. These unfortunate results are, in his opinion, largely due to the tendency of lumping together under the generic name of "Pott's" all fractures round the ankle-joint, without sufficient consideration of the lines of force which caused them. Cases of lameness and disability caused by these fractures come frequently to my notice, and I have been struck by the apparent difficulty surgeons have in obtaining perfect soundness.

Take, for instance, the first degree of this condition: many a time does it come under observation as being a sprained ankle which is proving slow in recovery. This diagnosis is often due to the presence of adhesions, more likely to occur when there has been a fracture than when a simple sprain has been sustained. In dealing with cases of sprained ankle where no obvious bone lesion is present, the question as to whether the ankle turned outwards or inwards at the time of accident is of importance, since the first degree of fracture only occurs where there has been an abduction of the foot. A radiograph is advisable, more as a guide to prognosis than diagnosis, since treatment where displacement is negligible is practically the same as in a sprain, but the period of disability is prolonged.

In the second degree of fracture, though accurate splinting can bring about good results, yet it must be acknowledged that permanent lameness is far from uncommon; so much so that at one time in our police force the fact that a man had sustained a "Pott's" fracture was considered a bar to his further employment.

The third degree of this fracture would appear to offer enormous difficulty to a satisfactory result under manipulation, and quite recently, I have seen a case of this kind, where the resultant distortion and lameness was pitiable. The accident occurred early in February of this year, whilst the patient—a man of about 40—was walking through a Borneo jungle. The medical man tried to get reduction under anæsthesia, eventually putting the limb up in plaster-of-Paris. Three weeks later the patient was able to be removed to Jesselton, where a radiograph showed the position of the bones to be precisely as in Fig. 3 of Sir Arbuthnot Lane's paper. Another attempt was made at reduction without result. The patient became dangerously ill from shock; and after some weeks was sent to England with a note stating that he had sustained a fracture-dislocation of the right ankle. On examination the leg was found to be thin and emaciated, with limited flexion of the foot, intense muscular wastage of the thigh with contraction of the knee; the upper end of the tibia formed a projection over the instep, whilst the os calcis formed a corresponding curve behind. A further radiograph showed the position of the bones as before, but the formation of callus and the general condition of the joint made operative interference inadvisable. Treatment by massage and graduated exercises is now making the best of a bad job. The patient was inclined to find fault with the attention he had received in Borneo, but the result, although undoubtedly disastrous, was no worse than is seen in cases where greater facilities for treatment have been available.

Considering the doubtful results so often obtained by the present method of setting and splinting these ankle-joint fractures, I am convinced that reduction by the operation procedure described by Sir Arbuthnot Lane holds out an almost certain prospect of soundness, since an almost perfect apposition can be obtained by a knowledge of the mechanics involved in the causation of the fracture.

I am, Sir, yours faithfully,
Seymour-street, W., Oct. 15th, 1921. FRANK ROMER.

TEACHING "DEAF-MUTES" TO HEAR.

To the Editor of THE LANCET.

SIR,—In the annotation in your issue of Oct. 8th on the late Prof. Urbantschitsch's paper on the use of acoustic exercises in the education of deaf-mutes, you do not refer to the work on similar lines which has been independently carried out in England, and to which reference was made in my Croonian Lectures published in your columns about a year ago. At the Birmingham meeting of the Association of British Physicians in April of this year I showed seven "deaf-mutes," ranging in age from 5 to 32, who were being taught to hear. All of them had been regarded as absolutely deaf both by their parents and by well-known aural surgeons who had seen them with me, but as they all showed normal vestibular reactions, I thought their deafness was probably functional. After periods varying from a year and a half in one case to between two and six months in most of the others considerable improvement had occurred. Each of the patients was now able to hear a large variety of sounds; one of them could hear the clicking of coins at a distance of 30 feet. Each could recognise and understand a considerable number of words, and four of them were able to carry on a conversation, when sentences were spoken slowly and in a loud voice close to their ears. Two of the children are having all their ordinary lessons by ear instead of by lip-reading.

Improvement has so far been continuous, though slow, and I think that there is a good prospect that the more intelligent among them will eventually learn to hear sufficiently well to enable them to carry on ordinary conversations.

I am, Sir, yours faithfully,
ARTHUR F. HURST.
New Lodge Clinic, Windsor Forest, Oct. 11th, 1921.

OCCUPATIONAL THERAPY IN HEART DISEASE.

To the Editor of THE LANCET.

SIR,—When a diagnosis of heart disease has been made in a child the questions arise of the scope and direction of the child's education, and of the extent to which games may safely be indulged in. For the adult with permanent cardiac disability advice is needed with regard to suitable occupation; the value to the individual of every year of even a restricted working capacity is apparent, not only in the light of the achievements of the phthisical Keats and R. L. Stevenson, the blind Milton and the epileptic Napoleon, but also with regard to recent post-war experience of occupational therapy, which enables blind and otherwise crippled men to find a place in industry, and thereby enjoy a measure of contentment. That a great deal can be done in this direction is shown in a recent contribution to the *Modern Hospital*, January, 1921, by Dr. F. L. Brush, medical director of the Burke Foundation, White Plains, N.Y., in a paper mainly based upon experience of over 2500 cases of heart-disease, of which more than 2000 had valvular deficiencies.

The plan followed by Dr. Brush may be briefly outlined. The first thing is to undo the effect of wrong advice "of physicians, relatives, employers, teachers," replacing "don'ts and can'ts by do's and can's." The patient recovering from acute disablement is given light hand-work in bed or chair and exercised up to fitness for transfer to a convalescent home, where he goes through four to nine weeks of gymnastic exercises, increasingly active physical play and grade walking, diversional occupation, and short hours of actual work about the institution, often on a handicapped wage. Gradual advance to full-time employment in the institution with medical oversight leads later on to the former job or to another expertly chosen by the "follow-up" agency. The author indicates the various occupations for which his patients have become fitted, such as gardening and carpentry for men and needlework for women. Dr. Brush advises the continuance

Dr. William F. R. Burgess, O.B.E., has been elected Master of the Society of Apothecaries.

Pharmaceutical Society of Ireland.—At the annual election of officers held on Oct. 11th a medical man, Mr. Alfred Barnes, L.A.H., of Dublin, was chosen as the new President.

Literary Intelligence.—The Dictionary of Practical Medicine, edited by Sir Malcolm Morris, Prof. Frederick Langmead, and Dr. Gordon Holmes, is announced for publication on Oct. 27th by Messrs. Cassell and Co.

Manchester Cathedral: Annual Medical Service.—At the annual service for the medical and nursing professions, held at Manchester Cathedral on Sunday last, there was a large attendance of doctors and nurses. The Archbishop of Armagh preached a stimulating sermon.

National Hospital for the Paralysed and Epileptic.—A bazaar will be held in the out-patient hall of the hospital on Founders' Day, Nov. 2nd, and will be opened by Lady Beauchamp at 3 p.m. The hospital will be open to inspection.

Hunterian Society.—The new session of the Hunterian Society will open on Wednesday, Oct. 26th, at 9 p.m., when Prof. E. H. Starling, F.R.S., will deliver the first Hunterian Society Lecture on "Some Heart Problems." The lecture will be delivered at the Sion College, Embankment, London, E.C. All members of the medical profession are cordially invited to be present.

Selborne Society.—A dinner will be held on Oct. 25th at the Hotel Cecil. Viscount Grey, of Fallodon, Vice-president of the society, will take the chair and will speak about the scope of the Gilbert White Memorial scheme. Tickets (at 15s.) may be obtained from the Hon. Secretary and Treasurer, at The Hermitage, Hanwell, London, W. 7.

Federation of Medical and Allied Societies. The regular meeting of the Medical Council will be held at 12, Stratford-place, Oxford-street, London, W., on Tuesday, Oct. 25th, at 5 p.m. The agenda includes the preparation of evidence to be submitted at the panel inquiry; the consideration of the subject of control of conception in wedlock, whether knowledge on the matter should be promulgated, and, if so, what knowledge and by whom; any other business.

Bristol Medico-Chirurgical Society. — The forty-ninth session of this society was opened on Oct. 12th, the new President, Mr. Cyril H. Walker, delivering an inaugural address on Quackery in the Treatment of Ophthalmic Disease. He traced the course of irregular practice in this field of medicine from the earliest times until now, concluding with a plea for greater attention to eye diseases, and better facilities for their treatment by the family practitioner. The secretary, Mr. Stuart V. Stock, was able to forecast an interesting programme for the coming session.

King's College Hospital Listerian Society.—The inaugural address was delivered on Oct. 19th by Dr. Arthur Whitfield on the Gentle Art of Making Mistakes. On Nov. 2nd Mr. P. B. Atkinson will speak on Graves's Disease. The meeting on Nov. 16th will be devoted to a debate. On Nov. 30th Miss C. P. Francis will speak on English Medicine in the Middle Ages, and Dec. 14th will be a clinical evening. On Jan. 18th Dr. J. E. Hadfield will lecture on Psychotherapy in General Practice, and on Feb. 1st Mr. C. P. G. Wakeley on Defects in the Mandibular Arch. Dr. C. F. T. East will give an address entitled, "Maladies, Ancient and Modern" on Feb. 15th, and Mr. B. J. B. Devine will speak on the subject of Carcinoma on March 1st. March 15th will be a clinical evening. The president for the session is Dr. F. W. Tunnicliffe. The meetings are held at 8.15 p.m. on Wednesdays at King's College Hospital.

The Services.

NAVAL MEDICAL SERVICE.

Surg. Comdr. W. Bradbury to Durban (on comnug.).

ROYAL ARMY MEDICAL CORPS.

Maj. G. H. Stevenson retires, receiving a gratuity, and is granted the rank of Lt.-Col. Maj. T. Walcot, late temp. Capt., to be temp. Maj., and to relinquish the rank of Maj.

Temp. Lts. to be temp. Capts.: R. M. Walker, C. W. Bennett, and W. H. Steil.

Officers relinquishing their commns.:—Temp. Capts. T. Walcot (granted the rank of Maj.), H. N. K. Kevin, and E. L. Davey (retain the rank of Capt.), and Temp. Lt. G. L. Lyon-Smith.

TERRITORIAL ARMY.

Col. H. Burrows, T.A. Res., to be Col.

Lt.-Col. J. G. Martin, from R.A.M.C., T.A., to be Col. and A.D.M.S., West Lancs. Divn.

Lt.-Col. (Bt. Col.) C. T. Green, having attained the age limit, is retired, and is granted the rank of Col., with permission to wear the prescribed uniform.

Maj. S. F. St. J. Steadman, from Genl. List, to be Maj.

Majs. J. W. Slaughter and M. A. Archdale, having attained the age limit, are retired and retain the rank of Maj.

Maj. J. Orton, having attained the age limit, is retired, and retains the rank of Maj., with permission to wear the prescribed uniform.

Capt. G. E. Lloyd (late R.A.M.C.) to be Lt., and relinquishes the rank of Capt.

Capt. H. W. Read to be Maj.

Capts. A. E. Delgado and W. H. Kiep resign their commns. and retain the rank of Capt.

2nd W. Gen. Hosp.—Capt. P. R. Wrigley, having attained the age limit, is retired, and retains the rank of Capt.

TERRITORIAL ARMY RESERVE.

Lt.-Cols. E. H. Cox (from 3rd E. Lancs. Fd. Amb.) and C. W. Eames (T.A. Res.) to be Lt.-Cols.

Maj. H. W. Pritchard, having attained the age limit, is retired, and retains the rank of Maj., with permission to wear the prescribed uniform.

Capt. G. G. Johnstone, from 2nd Lond. San. Co., to be Capt.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned Officers:—

Army Medical Service.—Col. J. Clay, C.B.E. (Hon. Lt. in Army).

Royal Army Medical Corps.—Lt.-Col. C. O. Parsons, 2nd Welsh Fd. Amb., and Majs. J. H. Hobling, 2nd S. Mid. Fd. Amb., and G. B. Robinson, D.A.D.M.S., H. Counties Div.

ROYAL AIR FORCE.

Dental Branch.—Flight Lt. L. S. Kettlewell relinquishes his temporary commission on ceasing to be employed, and is permitted to retain the rank of Capt.

SULFARSENOL IN THE TREATMENT OF CONGENITAL SYPHILIS.

To the Editor of The Lancet.

Sir,—With reference to your annotation in The Lancet of Oct. 8th on our short paper on Sulfarsenol in the Treatment of Congenital Syphilis, the object of this paper was to compare the result of intramuscular injection of sulfarsenol with the intravenous injection of some of the older remedies. We stated in our paper that the clinical manifestations quickly disappear under treatment with sulfarsenol. The Wassermann reaction was used as the gauge of the efficacy of treatment rather than the disappearance of clinical manifestations, because it is considered by most authorities to be a very much more sensitive test. Indeed, clinical manifestations frequently clear up after a short course of mercury, but who would claim to have eradicated the disease by such treatment?

The results obtained at the Royal Hospital for Sick Children, Glasgow, with ante-natal treatment are not in accord with those referred to by Mr. McDonagh—we have not, however, been able to find any definite figures published by him. Of 15 mothers treated in this hospital, all the offspring born subsequent to treatment gave a negative Wassermann reaction with one exception, which gave, at the age of 7 years, a weakly positive reaction. Neither this case nor any of the others have as yet shown any clinical signs of syphilis. Six families have been followed for seven years and, with the exception noted, have all given a negative Wassermann reaction, and none of them show clinical manifestations.

Lastly, the results of our treatment of children under 1 year of age shows a marked declension from those obtained by intravenous treatment and the failure in these cases cannot be explained by a hypothesis based on Mr. McDonagh's findings. Why, therefore, should such an explanation be applied to our cases over 1 year of age?

We are, Sir, yours faithfully,
E. Crawford.
Geoffrey B. Fleming.

Royal Hospital for Sick Children, Yorkhill,
Glasgow, Oct. 12th, 1921.

REACTIONS AFTER SALVARSAN.

To the Editor of The Lancet.

Sir,—In an article in the *Arch. Int. Med.* on 9000 cases of syphilis treated at the Johns Hopkins Hospital, Baltimore, Dr. T. E. Moore and Dr. A. Keidel give some particulars of skin reactions following the treatment by salvarsan.[1] I imagine the case I report here is probably unique.

Mr. O. B. S., aged 22, came to me on June 28th, 1921, with a quite typical hard chancre. I gave him a series of injections of N.A.B., dose 0·75, and on Sept. 29th I administered his ninth injection. He was taking hyd. c. cret., gr. 2, three times daily without intermission for the whole time. On the morning of Oct. 7th he came in to see me with an erythematous rash all over him, including his face, wrists, and hands; it was accompanied by intense itching. I diagnosed urticaria and ordered him sodium salicylate, sodium bicarb., and ammonium carbonate. The same afternoon I had an appointment to give him his tenth injection of N.A.B. At 5 P.M., when I saw him again, he had not taken any of my mixture. In five minutes from the moment of the injection he remarked that the itching was less and on examination the "wheals" of the urticaria were noticeably less. In 15 minutes my patient said there was no itching, and on further inspection only pale pink patches remained in the place of the raised areas. Dr. Moore and Dr. Keidel speak of urticaria as a possible result of salvarsan injections. Here is a case of "nettle-rash" being dispersed by the same agent. I was unable to discover any cause for the skin condition.

I am, Sir, yours faithfully,
Leonard Myer, F.R.C.S.E.,
Hon. Surgeon to Out-patients, St. Paul's Hospital
Oct. 17th, 1921. for Skin and Genito-Urinary Diseases.

PRESENTATION TO SIR J. HALLIDAY CROOM.

To the Editor of The Lancet.

Sir,—May I, through the medium of The Lancet, bring to the notice of Sir Halliday Croom's old residents and clinical assistants that it has been decided, through a presentation, to show our gratitude to him. Unfortunately the earlier records are incomplete, and as secretary of the committee which has been appointed, I should be glad if those who were with him prior to 1890 and are willing to contribute would kindly send their names and addresses to me.

I am, Sir, yours faithfully,
Douglas Miller.

50, Northumberland-street, Edinburgh, Oct. 17th, 1921.

Obituary.

GEORGE WILSON, M.D., C.M., LL.D. Edin., M.A. Aberd., D.P.H. Camb.

On Sept. 11th, at his home in Colwyn Bay, the death occurred of Dr. George Wilson, who was a pioneer in the teaching of hygiene. The Public Health Act of 1872 raised much discussion on sanitary questions throughout the country, and the publication in 1873 of Dr. Wilson's "Handbook of Hygiene" received an immediate and cordial welcome. This was practically the first text-book on hygiene available for medical students and was, moreover, for many years the standard manual for candidates for the D.P.H. In the eighth edition, however, issued in 1898, Dr. Wilson introduced his somewhat heterodox views on bacteriology and the causation of disease, when the book lost much value as a text-book and no further editions were called for. Dr. Wilson had become a Master of Arts at Aberdeen in 1860 and proceeded for his medical education to Edinburgh, where he graduated M.B., C.M. in 1863, M.D. in 1872. He received the honorary degree of LL.D. of Edinburgh in 1894 and was a Fellow of the Royal Society of Edinburgh. He took the D.P.H. at Cambridge in 1891. When surgeon to the convict prison at Portsmouth in the early seventies Dr. Wilson made observations on the criminals under his charge and formed the conclusion "that four-fifths are directly or indirectly the victims of intemperance." His comment on the scale of diet then given for full labour in prisons was that the prisoners lost weight on it to an extent of about 13 lb. in two months and had to be continuously transferred to lighter work and re-transferred if a complete breakdown was to be avoided.

Dr. Wilson was medical officer of health for the Mid-Warwickshire Combined District for over 30 years, retiring in 1909. In 1906 he was appointed a Member of the Royal Commission on Vivisection. He was proud of this distinction and gave much time and labour to the work of the Commission. He appended to the Final Report issued in 1912 a lengthy Reservation Memorandum, but he signed the main report and declined to be regarded as a representative of the anti-vivisectionists. After his retirement Dr. Wilson travelled abroad for some years and then settled in Colwyn Bay. The eye troubles, caused by cataract, from which he suffered in his later years were only partially relieved by operation and his vision remained dim.

Dr. Wilson married twice but had no children. To his widow we offer sincere sympathy in her great loss.

The late Dr. William Edward Dixon.—Dr. W. E. Dixon, who died at his residence "Kirkee," West Worthing, on Oct. 10th at the age of 75, received his medical education at the Middlesex Hospital, where he afterwards became house surgeon and resident obstetrical assistant. He qualified M.R.C.S. Eng., L.S.A., L.R.C.P. Edin., and L.M., in 1878, and held the post of clinical assistant at the Royal London Ophthalmic Hospital, becoming F.R.C.S. in 1881.

The King and Queen have sent a present of fruit to the Chelsea Hospital for Women.

Births, Marriages, and Deaths.

BIRTHS.

BARKLEY.—On Oct. 10th, at Woodcroft, Weybridge, the wife of Dr. T. Yuille Barkley, O.B.E., of a son.

BULSTRODE.—On Oct. 9th, the wife of C. V. Bulstrode, D.S.O., M.D., of a daughter (stillborn).

CLARKE.—On Oct. 14th, at Victoria Square, Clifton, Bristol, the wife of Dr. Richard Clarke, O.B.E., of a son.

EGAN.—On Oct. 4th, at Quetta, the wife of Major W. Egan, D.S.O., R.A.M.C., of a son.

EVANS.—On Sept. 7th, at Ranikhet, United Provinces, India, the wife of Captain R. R. Evans, R.A.M.C., of a daughter.

MURDOCH.—On Oct. 12th, at West Hyde, Rickmansworth, the wife of J. Murdoch, F.R.C.S.E., of a son.

STANLEY.—On Oct. 11th, at Rue des Belles Feuilles, Paris, the wife of E. Gerald Stanley, M.S., F.R.C.S., M.D. (Paris), of a daughter (Jane Elliot).

DEATHS.

BETTERIDGE.—On Oct. 14th, 1921, at "Marystowe," 3, Priory-road, Kew, the residence of his son, Alfred Betteridge, late Secretary, West London Hospital, after a short illness.

DIXON.—On Oct. 10th, at Kirkee, Mill-road, West Worthing, William Edward Dixon, F.R.C.S. Edin., aged 75 years.

MOSLEY.—On Oct. 6th, at Shaldon, South Devon, Reginald Lawson Mosley, M.B., L.R.C.S.I., aged 64 years.

NORRIS.—On Oct. 10th, at Langley Lodge, Surbiton, Frank Baker Norris, M.A., M.D., B.C.Cantab., M.R.C.S.Eng., L.R.C.P.Lond., aged 55 years.

WROUGHTON.—On Oct. 7th, John Henry Wroughton, M.R.C.S., L.R.C.P.Lond., Basutoland Medical Service.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

SANITARY AND MEDICAL ADMINISTRATION IN BURMA.

THE report on sanitary administration[1] in Burma during 1919 commences by stating that "the total area and population in Burma proper under registration remained the same as in 1918," except for a slight adjustment in the boundaries of two districts. The birth-rate was 29·89 and the death-rate 31·09 per 1000, calculated on the census population of 1911, which was 9,824,390. For 1918 these ratios had been 33·01 and 39·59; and for the preceding quinquennium, 34·70 and 28·19. The birth-rate was lower than in any of the preceding ten years, and the death-rate higher than in any of these years, except 1918, when it had been 39·59 per 1000. The bulk of the population (8,713,297) are Buddhists, among whom the mortality ratio was 30·79. For Christians it was 22·59, and for Hindus 36·08. Cholera prevailed throughout the province, causing 13,260 deaths, which gives a mortality ratio of 1·35, contrasted with 0·56 for the preceding quinquennium. Pakokku, in Upper Burma, with 1296 deaths (8·16 per 1000), and Akyab, in Lower Burma, with 2270 deaths (4·30 per 1000), suffered most, but not a single district was free from this disease. Very hot weather, a late monsoon, and consequent scanty water-supply, played an important part in the spread of infection. Lieut.-Col. C. E. Williams, I.M.S., Sanitary Commissioner, who presents this report, alludes to the relative isolation of Tavoy and Mergui districts (with the comparatively low death-rates of 0·55 and 0·30 per 1000 for this disease), and of Sandoway (0·10), all in Lower Burma, as emphasising the fallacy of the theory formerly prevailing of the local origin of cholera infection, mainly depending upon soil and atmospheric conditions. These are obviously only secondary factors, though local conditions have a determining influence upon the spread of introduced infection. The outbreak of 1919 was more serious than in the years immediately preceding, and it is not reassuring to learn that "little headway has been made in most places in organising effective preventive measures. The provision of a protected water-supply has had a most beneficial effect in several towns. . . . The greater number of towns still await the provision of this important preventive work. . . . The organisation of effective preventive measures in rural areas is at present almost a hopeless task, in the face of the general ignorance and insanitary habits of the mass of the people, and of the absence of a rural medical and sanitary staff." Proposals have, however, been put forward on an unambitious scale for the organisation of preventive measures. Small-pox caused 3917 deaths (0·40 per 1000, compared with 0·05 in the preceding quinquennium); it was more prevalent in Upper than in Lower Burma, the respective mortality ratios being 0·67 and 0·20 per 1000. This was contrary to the usual course of events, the infection being almost always introduced through Rangoon. It is disquieting to learn that the case-mortality amongst vaccinated children was 78·12 per cent. at ages 1 to 5, and 55·14 per cent. at ages 5 to 10. Some doubt is thrown on the correctness of the returns. Compulsory re-vaccination at 14 years, if not earlier, and compulsory vaccination and re-vaccination of all immigrants to Rangoon by sea, is recommended. Plague caused 4397 deaths (0·45 per 1000, compared with 0·72 in the quinquennium). Rangoon, with 782 deaths (2·67 per 1000), and Mandalay, with 571 deaths (4·12 per 1000), suffered heavily, but the highest relative mortality (19·45) occurred at Minbu (in Upper Burma), closely followed by Thonzè (in Lower Burma), with 18·95 per 1000. Anti-plague inoculation and rat destruction are carried out. The increase in death-rate from fevers (12·22 compared with 10·31 per 1000 in preceding quinquennium) is explained by the presence of influenza rather than malaria. An interesting account is given of the suppression of an influenza outbreak in the Turkish prisoners' camp in November and December, 1919, at Meiktila (Upper Burma), by Col. A. H. Safford and Major T. G. Cheyne, R.A.M.C.

"The fall in daily admissions had commenced after four days of nasal and pharyngeal irrigation, and six days before inoculation was commenced—thus rendering the influence of the latter prophylactic measure uncertain; an outstanding feature of the case is the nearly absolute restriction of the field of infection to the occupants of the east section of the camp, although separated from the adjoining section only by a single line of open barbed wire fencing. This . . . points to the smallness of the radius through which air-borne infection of the disease can be carried."

---

[1] Rangoon: Superintendent of Government Printing, 1921.

Groupe Inter-Universitaire Franco-Britannique.—A dinner in honour of Mr. Raymond Poincaré, past President of the French Republic and former Rector of the University of Glasgow, will be held on Nov. 1st, at 7.15 P.M., at the Connaught Rooms, Great Queen-street, Kingsway, W.C. Applications for tickets, £1 5*s.* per head, should be made immediately to the Joint Hon. Secretaries, at 51, Anson-road, London, N.W. 2.

Midland Tuberculosis Meeting.—The first general meeting of the Midland Tuberculosis Sub-Group of the Society of Medical Officers of Health will be held at the Anti-Tuberculosis Centre, 44a, Broad-street, Birmingham, to-day, Oct. 22nd, at 3 P.M. It is hoped that all members of the Society of Medical Officers of Health actively engaged in connexion with tuberculosis work will attend this meeting. The business to be transacted includes the confirmation of the proposed rules, and the election of officers and committee for the ensuing year.

Eastbourne Ear, Nose, and Throat Hospital. The annual meeting was held on Oct. 7th. The existing premises were opened on March 2nd last, and in-patients were first received on April 6th. Up till July 31st—the end of the hospital year—the in-patients numbered 55. The out-patients for the full 12 months numbered 2415. The financial statement showed that the hospital was in a better position than last year by £700. The first year's working of the institution as a fully equipped hospital shows that the step taken by the governors was a wise one.

Tuberculosis in Gloucestershire.—At the weekly luncheon of the Gloucester Rotary Club held on Sept. 30th, Dr. Arnott Dickson, county and city tuberculosis medical officer, gave an account of the campaign of public health authorities against tuberculosis, in the course of which he said that although the mortality from that cause was diminishing, there was still some justification for John Bunyan's description of consumption as "Captain of the Men of Death." Eighty per cent. of children were infected at the age of 14, and it was of extreme importance to ensure that the immunity which the child struggled to acquire should be strengthened into a bulwark for the rest of life. It was unfortunate that the Tuberculosis Order of 1912–13, suspended on the outbreak of war, had not been revived, and that the distribution of milk from cows with advanced tuberculous disease was still permitted. The question of housing, again, was of the very greatest importance; a large number of families simply did not get a chance of living healthy lives. While the outlook in tuberculosis work was encouraging, there was in the present state of knowledge no justification for expecting any immediate or sensational defeat of a disease which was almost an inherent defect of civilisation.

Royal Victoria Hospital, Belfast: Opening of the Session.—The present session was opened on Oct. 13th, when Colonel A. B. Mitchell occupied the chair and the opening address was delivered by Dr. H. L. McKisack. After welcoming the students and alluding to the changes in the staff during the past year, the speaker referred to the retirement of the late superintendent, Colonel A. Deane, and spoke appreciatively of his long services to the hospital. He extended a cordial welcome to his successor, Colonel J. V. Forrest, C.B., C.M.G. He referred to the foundation of the new dental department in the hospital, and alluded to the grave results which were now known to accrue from oral sepsis. A knowledge of dentistry was important not only for practising dentists, but also for the general practitioner. He wished to emphasise the fact that clinical instruction is the heart and kernel of the Ars Medica, while welcoming all the recent developments of laboratory methods. It was a liberal education in itself, developing the powers of observation and induction, and cultivating the judgment. The student must first study the normal individual and the condition of the healthy organs. Next he must learn the main facts of disease from his teachers and his text-books, and thirdly, he must exercise his own powers of observation and inquiry. He urged the importance of students becoming residents in hospital, and being in constant contact with the phenomena of disease. The student should acquire the habit of tabulating his own experience, and correlating it with the information afforded by his teachers. Experience to be of permanent value must be organised and sifted, otherwise it was a case of heaping ignorance upon ignorance. The student must cultivate the spirit of curiosity and inquiry and never hesitate to ply his teachers with questions. The young must carry forward the torch of research and education, and cherish the hope that they may be privileged to add something to the weapons for the endless war to be waged against disease. A vote of thanks to the speaker was passed on the motion of the chairman.

Dr. Lloyd Roberts's Art Bequest to Manchester.—The bequest of paintings, mezzotints, drawings, glass, china, and silverware of the late Dr. Lloyd Roberts has been formally handed over to the Manchester Corporation. The collection, which occupies four rooms in the Art Gallery, is of great value and distinction, and was opened to the public on Oct. 12th.

Treatment of Early Tuberculosis in Bristol.—On Oct. 5th Sir William Treloar formally opened the Frenchay Park estate, purchased by the Bristol city council to provide for the open-air treatment of early tuberculous children. The buildings already standing will, it is hoped, provide accommodation for as many as 35 children, and will be used until it has been found possible to build wards to take 100 beds. In the meantime Bristol is still without suitable premises for the treatment of "surgical" tuberculosis, and has to be content with sending a few patients to Alton.

St. Thomas's Hospital Medical and Physical Society.—Meetings of this society are held in the Club Reading Room at 8.30 P.M., under the presidency of Mr. J. E. Adams. The programme for the session is as follows. On Oct. 27th Dr. R. C. Jewesbury will speak on Child Welfare. On Nov. 10th a clinical and pathological evening will be held, and on Nov. 24th a mock trial on "A Case of Malpraxis." On Dec. 8th a clinical and pathological joint meeting will be held jointly with Guy's Hospital Physical Society at St. Thomas's Hospital. On Jan. 12th a discussion, "That Agitation is Essential to Progress," will take place, and on Jan. 26th a clinical and pathological joint meeting with Guy's Hospital Physical Society will be held at Guy's Hospital. On Feb. 9th Dr. Charles Singer will lecture on Medicine among the Ancient Greeks. Feb. 23rd and March 23rd will be devoted to clinical and pathological evenings, and on March 9th Sir A. Conan Doyle will address the society on Science and Psychology.

Leeds and West Riding Medico-Chirurgical Society.—The first meeting of the session was held at the Leeds General Infirmary on Oct. 14th, when Sir Berkeley Moynihan, the new President, occupied the chair. There was a very large attendance of members. Amongst a number of interesting cases and specimens on view Mr. Carlton Oldfield showed a specimen of ovarian gestation. At the conclusion of the discussion on cases, the President delivered an opening address on Medicine in Art. A large number of lantern slides, illustrating the portrayal of diseases and deformities in the works of the great masters, were shown by the speaker, who gave a most lurid and eloquent exposition of his subject. The address was listened to by an interested and enthusiastic audience.

Clinical Society of Manchester.—The Committee of the Clinical Society of Manchester have determined to devote the future meetings of the society to the demonstration and discussion of the latest methods of scientific investigation and their practical bearing on clinical medicine; this new departure is the result of a feeling that the usefulness and scope of a society hitherto devoted to discussion of unusual and difficult cases has been diminished by the post-graduate courses, &c., now held in several Manchester hospitals. The proposed syllabus for the coming session is as follows: (1) Physiology (November)—respiratory problems more especially associated with the composition and chemistry of alveolar air; (2) Pathology (January)—the Wassermann reaction and other blood tests; (3) Physiology (March)—special meeting at which an eminent physiologist will be invited to read a paper on the bearings of modern physiology on clinical medicine; (4) Pharmacology (May)—the digitalis group; (5) Anatomy (July)—nerve injuries.

Alvarenga Prize.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga prize (value about $300) will be made on July 14th, 1922, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays may be upon any subject in medicine, but must not have been previously published. MSS. must be typewritten, and if written in a language other than English should be accompanied by an English translation; they must be received by the Secretary of the College on or before May 1st, 1922. Each essay must be sent without signature, but plainly marked with a motto, and accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the College; other essays will be returned upon application within three months after the award. The Alvarenga prize for 1921 has been awarded to Dr. John W. Churchman, N.Y. City, for his essay entitled Selective Bacteriostasis of Gentian Violet.

Racial Difficulties.

With the arrival of the Indian Expeditionary Force difficulties arose, for the Medical G.H.Q. of the I.E.F., which assumed control of the East African Force, based its attitude towards the African native on a knowledge of East African stretcher-bearers, recruited from the porter class and very inferior to the personnel of the Uganda unit. After representations had been made by the Governor of the Uganda Protectorate the status of "troops" as opposed to that of "followers" was conferred upon what now became the Uganda Native Medical Corps. When this status was authorised it was by no means easy to secure its recognition by Europeans; many whites who had come to the country for the first time were disposed to regard all natives as of one class; complaints were made, and the final result was the establishment of a much larger corps energetically recruited from the missionary societies' secondary school pupils. Prince Joseph Musanje, a cousin of the Kabaka (King) of Buganda, was gazetted to the corps and the latter was drafted to Dar es Salaam in July, 1917. The distribution of the corps throughout the East African Force had a considerable effect on the hospital services. The expanded organisation contained representatives of nearly all tribes of British and of the then German East Africa; the total number of natives dealt with was about 1700, and the total deaths numbered 113, of whom one was killed in action and one died in the enemy's hands.

Characteristics of the Muganda.[1]

Sir Robert Coryndon, Governor of the Uganda Protectorate, has contributed to Major Keane's account a foreword testifying to the excellent work performed by the corps. A note on the form of training adopted is added by Major H. B. Owen, and extracts from Captain Tomblings' Diary of the Corps, with two appendices, complete the record. Major Keane himself refers in this way to the individual tribesman of his command: "The Muganda has a curious notion of what is manly, especially in regard to menial work, all forms of which he instinctively looks down on as degrading; hence considerable difficulty was experienced in inculcating the fact that all service to the sick, no matter how menial, was of a high order. His intense and fanatical pride of race renders him acutely sensitive to scorn, and apt to imagine insult where none is intended. With tactful and sympathetic handling there are few ordinary services which a Muganda will not perform in a manner that compels admiration. Of precocious intelligence, he can be a willing, cheerful, trustworthy, and industrious assistant. Unsympathetically handled he may be slothful, obstinate, sulky, or even mutinous, and utterly regardless of personal consequences."

"African Medical Education."

Relevant to this subject is an article entitled "African Medical Education," contributed to the October issue of *Mercy and Truth* (the record of the medical missions of the Church Missionary Society), by Dr. R. Y. Stones, who, during the last months of the war, served with the African Native Medical Corps, to which he brought experience in training West African Ibos in Nigeria, and Swahili and Wagongo in the Tanganyika Territory. Dr. Stones is convinced "that the average African makes a good dresser and war attendant, that he is able to learn simple dispensing, can give anæsthetics skilfully, and do routine microscopical work." By the title of his article, however, Dr. Stones does not refer to the training of Africans as medical men, but to the ability of the natives to acquire a certain amount of medical knowledge and thereby overcome the superstition and error in treatment of disease which at present exists among them.

MILK—AND WATER.

SOME 10 or 12 years ago the West Sussex County Council threatened to institute no further proceedings under the provisions of the Food and Drugs Act for the reason that the justices, even in glaring cases of violation of the Act, imposed only small penalties. Nowadays this offence is taken more seriously. On Oct. 10th a Steyning farmer was summoned for selling milk which was not of the nature and quality demanded by the purchaser. An inspector, on August 30th, stopped at the farm gate a lorry laden with milk for Southwick. Samples were taken, and that sent to the analyst showed there was only 3·63 per cent. of fat, 5·12 per cent. of non-fatty solids, and 36·2 per cent. of added water. Two days later the inspector paid a surprise visit to the farm and took samples of the milk actually drawn from the cows. One of these samples showed 5·85 per cent. of fat, 8·93 of non-fatty solids, and no added water. The farmer could offer no satisfactory explanation and was fined £20.

A DISAPPOINTED HOSPITAL.

AN announcement has appeared in the press which gives the impression that the bulk of the estate of the late Miss Annette Beaumont, of gross value £7626, is under the will of the deceased to accrue to the Chelsea Hospital for Women. This, unfortunately, is not the case. The amount is absorbed by debts, funeral, and other expenses, and not one penny will reach the hospital. It was hoped that the bequest might be available towards reducing the debt at present owed to the bankers.

THE USES OF DOG.

To the Editor of THE LANCET.

SIR,—With reference to your note in THE LANCET of Oct. 8th, in which it is suggested that it would be interesting to trace the origin of the therapeutic uses of dog, may I point out that the uses of dog were not unknown in ancient Arabian medicine? In the FitzPatrick lecture last year Prof. E. G. Browne mentioned a work by the Qádí Abu 'Alí at-Tanúkhí, who died A.D. 994, in which the following case is reported: An unnamed physician treated a boy, who was in great pain, with broth made from the flesh of a fat puppy. This was followed by melon, and later beer and hot water. On informing the patient as to the nature of the broth he was violently sick, with the result that he brought up a cattle-tick, which had evidently been swallowed with fruit! The tick, no doubt, having attached itself to the stomach, was the cause of the pain.

I am, Sir, yours faithfully,

Basle, Switzerland, Oct. 13th, 1921. T. F. M. SMART.

CHILD WELFARE IN FINLAND.

IN October, 1920, a league for the welfare of the children of Finland was founded on the initiative of General Mannerheim, having for its expressed aim the promotion and encouragement of voluntary effort in the sphere of child welfare, and the healthy development of the coming race. The constitution of the league admits of private and collective membership, the latter consisting of already existing local or national societies working in some special line of child welfare, or of local sections of the league, of which there are already 30. Private members are either active workers or contributors; the roll of membership already includes over 12,000 names. It is proposed in time to include in the activities of the league all the various branches of child welfare, but the Executive Council has decided, at the outset, to restrict its work to rigorously defined lines of action, and calls for immediate development on hygienic, moral, and educational lines, of infant welfare, and of the training of older children from the ages of 11 to 18. A substantial grant has been received from the National Exchequer for the organisation of courses for qualified nurses and midwives and others interested in maternity and child welfare; the continuance of the grant is dependent upon the success and continuance of this work. The league already has in operation a travelling bureau of information, and it is intended to establish a central consultative library in Helsingfors.

BRITISH SPAS AND FOREIGN COMPETITION.

AT the recent half-yearly meeting of the British Spa Federation held at Droitwich a leading topic of discussion was the Sunday closing of the baths now customary at Droitwich and other resorts, and its bearing on the whole question of foreign competition. In Droitwich spa authorities had been attacked on the score that the numbers of week-end visitors had diminished owing to the Sunday closing, and their action in that respect was defended by several speakers. It was contended that no hardship had been entailed on any one, that serious spa treatment demanded at least a two or three weeks' stay, that the rest-days frequently prescribed during treatment might well be arranged to fall on Sunday, that a whole day's rest was desirable for the staff of the establishment, and that in any case the expense of Sunday opening was prohibitive. At the same time it was acknowledged that English spas had much to do to compete with the foreign resorts, many of which were subsidised by their respective States, particularly—according to some speakers—in the matter of coöperation between spa managers, hotel proprietors, and members of the medical profession. From various speeches it was to be gathered that the meeting was generally in favour of Sunday closing of baths, and representatives of those resorts where they remain open had no encouragement to offer on that head. But it seems very doubtful if such an attitude will serve the British spas at a time when the Continental watering-places are striving their hardest to recapture their pre-war English visitors.

Erratum.—THE LANCET, Oct. 15th, 1921, p. 799. The Accuracy of the Formalin and Sachs-Georgi Tests for Syphilis. For W. Neave Kingsbury read A. Neave Kingsbury.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, Oct. 24th.

SECTION OF ODONTOLOGY: at 8 P.M.
Presidential Address by Mr. Montagu Hopson.
Mr. J. B. Parfitt: The Treatment of Pulpless Teeth.

Tuesday, Oct. 25th.

SECTION OF MEDICINE: at 5.30 P.M.
Dr. W. W. Payne and Dr. E. P. Poulton: Epigastric Pain.

Thursday, Oct. 27th.

SECTION OF UROLOGY: at 2.30 P.M., at St. Bartholomew's Hospital:
Operations by Mr. Girling Ball.
At 5 P.M.:
Demonstration of Cases by Sir Thomas Horder in the wards.
At 8.30 P.M., at No. 1, Wimpole-street: *Presidential Address* by Sir Thomas Horder: The Medical Aspects of Some Urinary Diseases.

Friday, Oct. 28th.

SECTION OF STUDY OF DISEASE IN CHILDREN: at 5 P.M. *(Cases at 4.30 P.M.)*
Cases will be shown by:
Dr. J. Porter Parkinson: A Case for Diagnosis. Dr. E. Bellingham Smith: (1) Spleno-medullary Leukæmia; (2) Stricture of Œsophagus; (3) Syphilitic Infantilism with *Splenomegaly*.
Dr. Eric Pritchard and Dr. B. Whitchurch Howell: Case of Recurrent Purpura with Joint Lesions and Fractures.
Other cases will be shown.
Dr. Donald Paterson: Duodenal Ulcer in Infancy.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE: at 8 P.M.
Presentation of Jenner Medal to Sir Shirley Murphy by the President of the Section.
Dr. L. G. Haydon: Plague in Wild Rodents in South Africa.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Oct. 24th.—8.30 P.M., *Discussion on* The Modern Treatment of Diabetes (introduced by Sir Archibald Garrod), followed by Sir William Willcox, Dr. O. Leyton, Dr. W. Langdon Brown, Dr. Edmund Spriggs, Dr. E. P. Poulton, Dr. George Graham, and Dr. P. J. Cammidge.

HUNTERIAN SOCIETY, at Sion College, Embankment, E.C.
WEDNESDAY, Oct. 26th.—9 P.M., First Hunterian Lecture:—Prof. E. H. Starling, F.R.S.: Some Heart Problems.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.
Museum Demonstrations in the Theatre of the College for Advanced Students and Medical Practitioners:—
MONDAY, Oct. 24th.—5 P.M., Prof. S. G. Shattock: Papilloma and Adenoma.
FRIDAY.—5 P.M., Sir Arthur Keith: Effects following Disordered Action of Thyroid (illustrated by lantern slides).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Oct. 24th.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 2 P.M., Dr. S. Pinchin: Medical Out-patients. Dr. Morton: X Ray Department. 2.30 P.M., Mr. Addison: Visit to Surgical Wards. 5 P.M., Dr. A. Saunders: Lecture:—Gastric and Duodenal Ulcer.
TUESDAY.—10 A.M., Mr. Steadman: Dental Department. 11 A.M., Dr. McDougal: Electrical Department. 12 noon, Mr. Sinclair: Surgical Treatment of Gastric and Duodenal Ulcer. 2 P.M., Mr. Tyrrell Gray: Demonstration of Cases in Surgical Wards. Mr. Banks Davis: Diseases of the Throat, Nose and Ear. 5 P.M., Dr. Cole: Lecture:—The Treatment of Early Mental Disorder.
WEDNESDAY.—10 A.M., Mr. MacDonald: Genito-Urinary Department. 2 P.M., Dr. Burnford: Demonstration of Cases in Medical Wards. Mr. D. Armour: Visit to Surgical Wards. Mr. Tyrrell Gray: Operations. Mr. Gibb: Eye Department. 5 P.M., Dr. Burnford: Lecture:—B. Coli Infections.
THURSDAY.—11 A.M., Dr. Simson: Gynæcological Demonstration. 2 P.M., Mr. MacDonald: Surgical Out-patients. Mr. D. Armour: Operations. Mr. Simmonds: Orthopædic Department. 5 P.M., Dr. Snowden: Lecture:—Simple Methods of Psychological Treatment.
FRIDAY.—2 P.M., Dr. Burrell: Medical Out-patients. Mr. Sinclair: Surgical Out-patients. Dr. Pernet: Skin Department. 2.15 P.M., Mr. Addison: Operations. 2.30 P.M., Dr. Pritchard: Demonstration of Cases in Medical Wards. 5 P.M., Dr. Cole: Insanity and Heredity.
SATURDAY.—10 A.M., Dr. A. Saunders: Medical Diseases of Children. Dr. Burnford: Visit to Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. Mr. Simmonds: Surgical Out-patients.
Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M., In-patient, Out-patient Clinics and Operations.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART POST-GRADUATE COURSE, Westmoreland-street, Marylebone, W.
MONDAY, Oct. 24th.—11 A.M., Dr. Goodall: Out-patients. 2 P.M., Dr. Moon: In-patients. 5.30 P.M., Lecture:—Dr. P. Hamill: Diseases of the Myocardium.
TUESDAY.—10 A.M., Dr. Parsons-Smith: Out-patients. 11 A.M., Dr. Price: In-patients. 2 P.M., Sir S. Russell-Wells: Out-patients.
WEDNESDAY.—10 A.M., Dr. Parkinson, 2 P.M., Dr. Moon Out-patients.
THURSDAY.—2 P.M., Dr. Price: Out-patients. Dr. Moon: In-patients. 6.30 P.M., Dr. Hamill: Out-patients.
FRIDAY.—10 A.M., Dr. Parsons-Smith: Out-patients. 2 P.M., Dr. Parkinson: Out-patients. 3 P.M., Dr. Parkinson: In-patients. 4 P.M., Dr. Goodall: In-patients.
SATURDAY.—10.30 A.M., Dr. Hamill: In-patients.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Oct. 27th.—4 P.M., Lecture:—Dr. Theodore Thompson: Some Functional Disorders of Childhood.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.
Post-Graduate Course on Infant and Child Welfare.
A Course of Twelve Lectures on the Management and Feeding of Infants and Young Children, by Dr. E. Pritchard, to Qualified Practitioners.
WEDNESDAY, Oct. 26th.—6 P.M., Lecture VII.:—The Management of Difficult Cases.
FRIDAY.—6 P.M., Lecture VIII.:—Treatment of Minor Ailments.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.
THURSDAY, Oct. 27th.—6 P.M., Chesterfield Lecture:—Dr. W. K. Sibley: Electrical Treatments, X Rays.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE CLINIC.
TUESDAY, Oct 25th.—4.30 P.M., Dr. D. E. Core: Differential Diagnosis of Disseminated Sclerosis.

ST. MARY'S HOSPITALS POST-GRADUATE LECTURES, Whitworth-street, West Branch, Manchester.
FRIDAY, Oct. 28th.—4.30 P.M., Dr. Donald: *Lacerations of* the Genital Tract.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street, Whitworth Park.
THURSDAY, Oct. 27th.—4.15 P.M., Dr. A. C. Magian: Dysmenorrhœa.

UNIVERSITY OF SHEFFIELD.—FACULTY OF MEDICINE.
Post-Graduate Lectures and Demonstrations.
TUESDAY, Oct. 25th. (At the Royal Infirmary.)—3.30 P.M., Mr. A. Cuff: *Acute Abdomen.* 4.15 P.M., Dr. A. G. Yates: Demonstration of Cases of Intracranial Syphilis.
FRIDAY. (At the Royal Hospital.)—3.30 P.M., Dr. E. F. Skinner: Dermatological Cases. 4.15 P.M., Mr. G. S. Simpson: *Demonstration of Cases.*

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.
A Course of Eight Lectures and Discussions on Problems of Public Health in Relation to Industrial *Hygiene* at the Lecture Theatre of the Institute.
WEDNESDAY, Oct. 26th.—4 P.M., Lecture II.:—Dr. R. M. Wilson: The Political Significance of Industrial Hygiene.

Appointments.

EASTWOOD, E. H., M.B., Ch.B.Liverp., has been appointed Demonstrator in Pathology and Bacteriology in the University of Sheffield.

PATRICK, J., M.B.Glasg., F.R.C.S.Edin., F.R.F.P.S.Glasg., a Lecturer in Clinical Surgery at the Royal Infirmary, Glasgow.

WARD, J. O., M.R.C.S., L.S.A., Certifying Surgeon under the Factory and Workshop Acts for Knottingley.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen University and North of Scotland College of Agriculture.—Physiologist. £600.
Aberystwyth Infirmary and Cardiganshire General Hospital.—Res. H.S. £250.
Albert Dock Hospital, Connaught-road, E.—Surg.
Barrow-in-Furness, North Lonsdale Hospital.—H.S. £225.
Bedford County Hospital.—Asst. H.S. £150.
Birmingham General Hospital.—Two H.S.'s. £100.
Brighton, Royal Sussex County Hospital.—H.S. Cas. H.S. and Anæsth. Each £140.

may be present without hæmatemesis or gastric disturbance over long periods in the evolution of the disease. A few cases are recorded with an anæmia of the pernicious type under circumstances in which there is no question of a diagnosis of the so-called idiopathic pernicious anæmia. It occurs in those cases in which the tendency to anæmia has been at work the longest time or in those whose anæmia has developed during the period of growth, especially congenital cases of acholuric jaundice.

5. Polycythæmia is a rare complication of chronic inflammation of the spleen. It is current opinion that chronic tuberculosis of the spleen is one of the infections of the spleen that produces it. Having carefully re-examined the evidence which we shall discuss later I cannot admit that there is in tuberculosis of the spleen any more, if as much, tendency to polycythæmia as in other conditions. Leaving aside the question whether there is a primary blood disease resulting in an enormous over-production of red cells and consequent passive dilatation of the spleen, there is no doubt that a secondary polycythæmia occurs caused by a chronic non-suppurative thrombo-phlebitis of the splenic and portal veins with obstruction, and that the spleen in these cases shows the general features of other inflammations.

6. The relation between splenic inflammations and leucocytosis and the more intense myelocytic reactions of the blood-forming tissues is very close, but cannot yet be fully explained. Cases are on record, *and most clinicians of experience are* aware, of the picture of splenic anæmia ultimately becoming leukæmia, especially in children. These may be said to have shown at first the aleukæmic stage of leukæmia or be in an intermission. On the other hand, many infections produce a temporary leukæmic reaction in the blood, *and* the possibility suggested by G. R. Ward cannot be disregarded—viz., that leukæmia is the reaction of the tissues to a specific organism exactly corresponding to the infectious leukæmia of fowls.[2] Apart from the special cellular reactions of the spleen in leukæmia the organ shows many of the features that are associated with splenic inflammations of known ætiology, such as fibrosis, atrophy of the normal tissue elements, hæmorrhage, thrombo-phlebitis, and infarction.

7. Relation to hepatic conditions. In explaining the mechanism of the production of hepatic inflammation, jaundice, and cirrhosis it is only necessary to state certain facts in order to be assured of their nature: (i.) the liver by its position in the circulation filters off from the splenic blood both particulate and soluble matter that may be discharged into it; (ii.) *the presence of chronic progressive* inflammatory disease in the spleen ultimately leads to chronic inflammatory disease (portal cirrhosis) in the liver, as Banti amply demonstrated many years ago; (iii.) the presence of a thrombo-angeitis in these spleens or in the veins draining them points out the mechanism whereby the materies morbi is transferred to the radicles of the portal vein in the liver; (iv.) in Gaucher's type of splenomegalia emboli of the characteristic spleen cells can be identified in the radicles of the portal vein. In tuberculosis also the transference of infective material from spleen to liver can be inferred; (v.) the removal of the spleen cures many cases in which the hepatic condition is not too advanced.

These facts amply explain the intimate connexion between splenic and hepatic inflammation. The fact that the liver lesion is a cirrhosis and not a specific granuloma that can be recognised as anatomically distinct rests on two facts: first, the emboli transferred from spleen to liver being produced in the radicles of the splenic vein are small; the lesion in the liver will therefore be small and may occur in all parts of the liver. Secondly, the liver is an organ whose power of destroying infective matter is very great—witness the fate of previous gummata in the common form of the botryoid liver, and the rarity of any but scattered miliary tubercles in post mortems from cases of generalised tuberculosis.

8. Hæmatemesis. Closely connected with this factor of embolism is the symptom of hæmatemesis, so common in some forms of splenomegaly. The origin of this sign is probably not always the same in every case; in the first place it may arise from stasis in the portal system and hæmorrhage from the œsophageal or other neighbouring veins, as in portal thrombosis [3] and in Laennec's cirrhosis; secondly, in spleno-portal embolism and thrombosis it is easy to imagine an embolus issuing from the spleen and becoming shunted along the vasa brevia or left gastro-epiploic vein to the stomach wall, where in one of their tributaries it might settle down to produce an inflammatory lesion and hæmorrhage. Moreover, it has been estimated (Mayo) that 40 per cent. of the blood in the splenic artery goes to the stomach. In confirmation of this I might mention that I have been able to produce *gastric ulcers and hæmorrhage* in a monkey by infecting it via the peritoneum with an organism isolated from a case of acholuric jaundice. In some cases it is possible that the anæmia is entirely due to the periodic loss of blood, as in the case recorded by Bland-Sutton,[4] where the return of the blood count to normal was a sure sign of impending hæmorrhage, the causation in this case being an organised thrombosis in the portal vein.

From an inflammation in the spleen there may therefore occur, from time to time, a transference of the organic cause, sometimes as bacteria only, sometimes with the tissue and inflammatory elements of the lesion, leucocytes, fibrin, catarrhal endothelial cells, in the form of minute emboli. This transference implies an inflammatory lesion in the liver which we *know appears ultimately as portal cirrhosis*; but in the more active stage it is conceivable that a local or general catarrhal hepatitis occurs leading to jaundice. As we shall see later certain forms of splenic inflammation are more frequently associated with jaundice than others. The other hepatic symptom, ascites, is rare in primary splenic disease, only occurring when the liver is grossly cirrhotic or when the portal vein is markedly obstructed.

CRITERIA OF CAUSATION.

Splenic inflammation and its consequent action on bodily tissues may conceivably be caused by a toxin originating in and dependent on the elements of splenic tissue only—as may be true of the thyroid in exophthalmic goitre and of the kidney in uræmia. On the other hand, it may come from the action of an organism on splenic time and the efforts of the spleen in repair. There is no evidence at present available that the spleen of itself produces an internal secretion which is deleterious under any circumstances. The body compensates at once for loss of the spleen, and splenic enlargements and inflammations occur without any effect on the body. I am frankly sceptical about any ætiology which implies some undemonstrated non-bacterial toxin secreted by an abnormal metabolism of some splenic tissue. It were better to proceed, even at the risk of ignoring such possibilities, from the known effect of invasion of the spleen by a pathogenic organism to those groups of cases whose causation is uncertain. Therefore, my working rule, which bids fair to be more fruitful of practical results than any other, is to suspect all splenic enlargements of an inflammatory type as being caused by extraneous organisms until proved otherwise.

For instance, we have now very adequate and complete knowledge that primary splenomegaly with inflammation in malaria, kala-azar, tuberculosis, and syphilis, are all due to the specific organisms of those diseases. There is little doubt, moreover, that the splenic form of Hodgkin's disease is of bacterial origin, though the organism itself is not certain. Therefore, in attempting to explain splenic inflammations in the same manner as those of known ætiology, we are making no assumption for which there is no analogy.

What criteria must be fulfilled in order to accept that a given organism is the cause of the splenic condition? In the first place it is necessary, *especially in new work, if possible, to fulfil Koch's* postulates that the organism must be isolated in pure culture from the individual affected, that it shall be cultivated outside the body, and that on injection into animals it shall produce and be contained in the lesions following introduction into an animal. These are very rigorous tests, and in some human disease whose causation is generally agreed upon they have not been fulfilled. The reason for raising this point here is to draw attention to the very loose way in which many reports of cases are presented. In reporting a case as syphilis of the spleen, for instance, we must carefully distinguish between the lack of certainty of the clinical diagnosis—even aided by morbid anatomy—and the scientific diagnosis that fulfils all logical desiderata. This has been most evident to me in going over again the evidence for the causation of the reported cases of splenomegaly due to tuberculosis *and syphilis*; *some authors rely* on a mere naked-eye diagnosis of tuberculosis at the post mortem, others give microscopic results but make no mention of the presence or not of bacteria. In syphilis the reports are even more uncertain.

The total number of prisoners of war (average strength for two months, November and December) was 6300. Of these 2300 were in the East Camp, among whom there were 501 cases and 32 deaths. Only four or five cases occurred among the remainder (4000) in the adjacent camp to the West. The treatment consisted in gargling, nasal douching, and inoculation. Progress is being made as regards sanitation in various directions, and it is stated that the aerobic filter latrine continues to increase in official and public estimation. It has been shown to be well adapted for places with a heavy rainfall (over 200 inches), such as Moulmein and Akyab, and is considered to require the minimum of labour on the part of the conservancy staff to maintain it in a wholesome condition.

From the report on *Vaccination* for the triennial period, 1917–18 to 1919–20, it appears that the number of persons vaccinated increased from 491,274 in the first year to 838,237 in the third, and that the ratio of successful operations rose from 34·56 to 51·85 per 1000 of the population. The deaths from small-pox decreased from 0·24 to 0·05. The percentages of success in primary operations were 95·88, 97·83, and 97·53 in the three years respectively. Lieut.-Col. J. Entrican, I.M.S., officiating superintendent-general of vaccination, considers this to be on the whole a very fair result. Experiments were made to test the duration of vitality in the lymph under the ordinary conditions to which it is subjected. This was found to be three weeks, except in March, April, and May, when a fortnight, or even less, was the limit. No vaccination should be done during the hot weather months, unless the lymph can be used within 10 or 12 days of its issue (except in presence of a small-pox epidemic). The lymph used is always glycerinated. After many experiments a good method of closing the tubes without heat was evolved. The ends are plugged with a mixture of plaster-of-Paris, and a very concentrated solution of gum acacia, and afterwards dipped in a resinous mixture, impervious to air and moisture. After experimenting on various preservatives it was found that "glycerine still holds the field against all comers."

During the triennium 1917–19 the post of Inspector-General of Hospitals was held by Col. P. C. H. Strickland, I.M.S., who was succeeded by Lieut.-Col. Entrican in December, 1919, this latter officer presenting the report on *Hospitals and Dispensaries*. This refers to the three-year period, but contains the statistics of 1919 only, those for 1917 and 1918 having been already published. At the beginning of 1917 there were 282 hospitals and dispensaries of all kinds working in the province, and at the end of 1919 there were 269; 34 institutions had been closed and 21 opened during the triennium. Progress in hospital construction has been interfered with owing to war conditions, but there has been improvement in various ways, brick and tiled buildings taking the place of wood and matting, &c. A cheap and simple form, used in Ceylon, is recommended. It consists of a framework of iron on a concrete plinth, with single brick walls of four or five feet height, and a tiled or shingled roof. This does not meet the side walls, but is low enough to prevent rain beating in. The floor is cemented and cambered or curved, with openings in the side walls, so that it can be rapidly flushed and cleaned. The type seems to be well adapted for a climate such as that of Burma, where there is no cold weather. Instruments and appliances are somewhat out of date in many hospitals, and Col. Entrican suggests that it would be an excellent thing if some of the medical and surgical equipment available in England, after demobilisation of war hospitals, could be procured to improve the equipment of Indian hospitals. He mentions good modern splints, and a Harcourt chloroform inhaler as especial desiderata.

The total number of patients treated in the three years under consideration at the public hospitals and dispensaries amounted to 6,256,943, being an increase of 197,519 over the preceding triennium. Of this total 285,363 were indoor patients, the beds available at the end of 1919 being 6152, compared with 6321 at the end of 1916. The percentage of the total population of Burma treated was 17·37 in 1917, and 16·89 in 1919. Unfortunately all travelling dispensaries had to be closed down except one. Col. Entrican considers that a well-staffed and equipped central hospital at headquarters, with a travelling dispensary and motor ambulance transport for each township, would be a sounder method than the multiplication of small hospitals and dispensaries. There is need for segregation hospitals for infectious disease throughout the whole province, but it is considered that all infectious diseases, except small-pox, could be safely treated in segregation wards in the compound of a general hospital, provided plenty of room were available.

There are indications that leprosy is much more widespread than is generally believed, especially in Rangoon, among the Chinese community. It is stated "that the Lepers Act is a dead-letter in most municipalities. . . . A large number of pauper lepers wander about the country from one small bazar to another, and at present it is impossible to stop them." There was considerable overcrowding at the Rangoon General Hospital, the in-patients admitted having numbered 8786 in 1919, and the daily average in hospital, 472; while the number of beds was nominally only 443. This has been due partly to admission of chronic and incurable cases, which should be treated elsewhere. The largest number of admissions to hospital throughout the province, in 1919, was for injuries (15,313), and after this for malaria (12,026), not, however, of a severe type, as the percentage of mortality was only 2·95, and for the three years averaged 2·68. It is stated also that a large number of cases at present called malaria are wrongly so diagnosed. Cholera caused 1275 admissions, with a death-rate of 51·29 per cent. during the triennium. It is thought that this heavy death-rate may be considerably reduced by the adoption of Sir Leonard Rogers's method of treatment. At Myaungmya nine recoveries were reported out of ten cases so treated. There were 1553 admissions for small-pox, with 380 deaths in 1919, a large increase over the two preceding years; 1122 of the cases (with 289 deaths) occurred at Rangoon; as to this it is stated that the majority were either imported or arose from contact with imported cases. Among the unvaccinated the death-rate was 36 per cent., among the vaccinated (including all doubtful cases, when the patient was said to have been vaccinated, even if no marks were found) it was 15 per cent. The Pasteur Institute shows a steady increase of patients; of 1154 persons treated in the three years, only four (0·35 per cent.) died.

The report on *Lunatic Asylums* (1921) refers to the triennial period 1918–20. The Rangoon asylum accommodates 632 patients, and that at Minbu, in Upper Burma, 136. The latter is a converted jail, and the floor space per head is only 36 square feet. Another asylum, at Kokine, is expected to be ready for occupation during the present year. The average number of inmates in the two institutions rose from 816 in 1918 to 856 in 1920. The death-rates in the Rangoon asylum, calculated on the daily average strength, were 8·81, 10·77, and 7·57, in the three years, 1918–19–20, respectively, the chief causes being tuberculosis, pneumonia, and dysentery.

The daily average number of prisoners in the various *Jails* in Burma was 13,388 in 1919, and 14,607 in 1920, these figures being lower than in any previous year since 1910, except 1918, when the average number was 14,068. The admissions to hospital, the daily sick, and the deaths were 314·41, 19·64, and 28·53 per 1000 in 1919; and in 1920, 437·12, 21·50, and 19·92. The increase in admissions for 1920 was chiefly due to influenza. Cholera was present in Burma during 1919, but only three jails were affected, that at Myingyan having 53 cases and 31 deaths. Dysentery was unduly prevalent, with 31·49 per 1000 admissions and 3·89 deaths in 1919, and corresponding ratios of 35·03 and 3·24 in 1920. "Bowel disease" was prevalent throughout Burma in 1919, and Major H. H. G. Knapp, I.M.S., the Inspector-General of Prisons, notes that in many places there was a great plague of flies, which he considers to have had a causal connexion. Special pains were taken to tackle these vectors; and at Mandalay, from June to December, well over a million were killed by prisoners. They could not have been better employed. There was some increase of enteric fever in 1920 (30 cases and 15 deaths). Fifteen cases occurred at Insein, but the source of infection could not be traced. Ankylostomiasis was considerably more prevalent in 1920 than in the previous year, 896 cases and 9 deaths, as compared with 741 cases and 12 deaths. Search for ova and worms, and treatment of the infected were carried out more rigorously. At Akyab the infection rate was found to be 46·65 per cent., and at Prome 30 per cent.

THE AFRICAN NATIVE AND MEDICAL SERVICE.

UNDER the title "The African Native Medical Corps in the East African Campaign"[1] Major G. J. Keane, of the Uganda Medical Service, and Captain D. G. Tomblings have compiled an interesting account of the work performed by a corps recruited from one of the most intelligent and highly developed of African peoples. On the outbreak of hostilities sanction was obtained for the engagement of 40 natives as the Uganda Stretcher Bearer Company—the germ of the corps which later numbered 10 British R.A.M.C. officers and other ranks, and 1500 natives. At first the Uganda administration furnished men largely of the peasant class, who proved unsatisfactory; they were replaced by a number of volunteers—boys from the Mengo High School (Church Missionary Society), and from the Government centre at Kampala, where, prior to the war, general medical training was carried on, with particular regard to anti-venereal measures. These men soon became efficient in elementary first-aid, nursing, and stretcher drill.

---

[1] London: Printed by Richard Clay and Sons.

æstivo-autumnal fever, and showed a negative W.R., it is likely that malaria played a part in causation.

10. Bernard.[14]—Quotes a case of mild splenomegaly and jaundice, appearing several years after a syphilitic chancre, and rapidly cured by mercury.

The next series are taken in their chronological order:

11. Coupland.[15]—Female with splenomegaly and anæmia had splenectomy and improved markedly. Two years after the operation the patient died from hæmatemesis and ascites. The liver at the post-mortem was much scarred and typically syphilitic. The spleen showed fibrous atrophy of the corpuscles and numerous hæmorrhages.

12. Fuhs.[16]—*Female, aged 17, having had five years'* history of a painful abdominal swelling; progressive weakness and loss of energy with occasional epistaxis. The blood, showing a chlorotic anæmia with 5500 whites, was restored to normal after operation for splenectomy, the W.B.C. being 11,000. W.R. was *positive*; *spleen showed caseous areas.*

13. Queyrat.[17]—Male aged 24, syphilis five years before; enlarged liver and spleen, ascites present. W.R. blood and ascitic fluid was positive. No blood counts are given.

14. French.[18]—Male, aged 54, whose blood had been positive on several occasions with the clinical picture of pernicious anæmia; R.B.C. 1,900,000, W.B.C. 21,000, Hb 20 per cent., C.I. 0·5. No benefit from salvarsan and other syphilitic remedies. Excision of spleen caused rapid amelioration of anæmia to 86 per cent. Hb. A sister of the patient had a very similar condition.

15. Hartwell.[19]—Male with severe secondary anæmia and hæmatemesis; W.R. strongly positive; antisyphilitic remedies produced no improvement, but excision of the spleen caused immediate betterment and the Hb rose from 25 per cent. to 80 per cent. The trabeculæ were much thickened and there were large and numerous follicles with fibrosed centres.

16. Osler.[20]—Female, aged 22, had had obscure abdominal illness at 15 years; blood picture of leukæmia. Post-mortem, liver of hepar lobatum type with fibrous gummata projecting into the capsule. The spleen, 23 × 16 cm., had slight adhesions, was dark red on section, with no trabeculæ or Malpighian bodies to be seen.

17. Osler.[20]—Male, aged 34, with a history of syphilis, having had jaundice and dropsy three years previously; R.B.C. 1,400,000; W.B.C. 7500.

18. Osler.[20] Male, aged 11, history of nodes on skin and arthritis of left knee three years before. Several children in family were dead, but there was no clear syphilitic history. Liver enlarged and irregular, spleen very large, blood count practically normal three months before; later count showed R.B.C. 5,770,000, W.B.C. 4000, Hb 65 per cent.; W.R. negative; increasing ascites; after a hæmatemesis followed by melæna R.B.C. 2,000,000; much blood in stools. Post mortem, anæmic organs, œsophageal varices, one of which had caused the bleeding. Enlarged spleen with dense capsule and much internal fibrosis. The liver was grossly cirrhotic and deformed with large islands of newly-formed liver substance.

19. Stevenson.[21]—Female, aged 22, who from 9 years had had attacks of epistaxis and gastro-enteritis. The mother had syphilis and had had two abortions previous to the patient's birth. For one year she had been very anæmic with an enlarged liver and spleen. R.B.C. 1,500,000, W.B.C. 4568, Hb 83 per cent. W.R. not recorded. Twelve days after excision of the spleen the blood showed R.B.C. 4,400,000, W.B.C. 11,200 and Hb 83 per cent. The microscopic section of the spleen showed lacunæ full of pale cells with and without nuclei.

20. Hey Groves.[22]—Female, aged 40, who since infancy had had ill-health with attacks of vomiting and abdominal pain. There was free fluid in the abdomen, the urine was normal, but no mention is made of the W.R. R.B.C. 6,000,000, W.B.C. 16,000, Hb over 100 per cent. Splenectomy did not give relief; there was recurrent ascites after the operation. The liver was found to be grossly deformed.

21. Giffen.[7] Case 2.—Female, aged 32, with moderate splenomegaly and anæmia of the secondary type without leucocytosis. The liver at the operation contained palpable gummata and was cirrhotic. There was no hæmatemesis, no history of syphilis, but the W.R. was strongly positive. No improvement followed antisyphilitic treatment, but splenectomy effected a cure. There was moderate diffuse fibrosis of the spleen.

22. Caussade and Levi Franckel.[23]—Male, aged 26, suffering from gastro-intestinal symptoms with jaundice and a positive W.R. The spleen was enlarged and mercury treatment failed. The spleen showed fibrosis of arterial origin with peri- and end-arteritis. The liver showed cicatricial sclerosis. The blood count varied from 2,000,000 to 3,500,000 red cells and from 1000 to 4500 white cells.

23-8. Symmers, Gettler, and Johnson.[24]—Six cases, of which three had strongly positive Wassermann reactions: (*a*) female, aged 29, suffering from punched-out ulcers of both ankles from the age of 15, a large spleen, anæmia, of R.B.C. 3,500,000, W.B.C. 8200, Hb 69 per cent. The spleen, removed by operation, had a finely granular substance, dark red, an old healed infarct and several mineralised arteries which the authors believe to be characteristic of syphilis. The patient was cured by splenectomy, having previously been successfully treated for the leg ulcers by antisyphilitic remedies. (*b*) Male, aged 32, had a large spleen and ascites. R.B.C. 4,100,000, W.B.C. 3500, Hb 65 per cent. The spleen, removed by operation, weighed 1040 g., was "meat red" on section, finely granular, and cut with difficulty. The liver at the operation appeared finely granular. (*c*) Male, aged 45, with an enlarged spleen and ascites. R.B.C. 4,160,000, W.B.C. 5200. At the autopsy the liver was "gnarled" and a solitary gumma was present in the right lobe.

Characteristics of Syphilitic Splenomegaly.

Assuming a syphilitic origin in all these cases we may now sum up the characteristics of syphilitic splenomegaly. The anæmia tends to be of the chlorotic type, as in the typical splenic anæmia, and the red cell count drops to just over one million. French reports his case as having the clinical picture of pernicious anæmia, so severe was the anæmia, though chlorotic in type. Schulmann and Weissmann case had policythæmia. The white cell count varies. One of Osler's cases had the blood picture of leukæmia; in the other cases where counts are given the figures vary from 4560 per c.mm. in Stevenson's case to 16,000 in Hey Groves's case and 21,000 in French's. The leucocytosis recalls that after splenectomy for trauma we must have in mind the possibility that a spleen may be so damaged by disease that the same effect at compensation is demanded from other white cells in the body which we see after splenectomy. Further, such compensation having been established before operation, we should not expect such a marked leucocytosis afterwards.

As regards jaundice both Giffen's cases had suffered from it but it was not permanent. Attacks of jaundice are reported in Pollitzer's and Osler's second case. Four cases (Giffen (Case 3), Coupland, Hartwell, and Osler (Case 3)) are reported with hæmatemesis, and in two epistaxis is mentioned. Four cases are reported as having had ascites (Osler (Case 3), Coupland, Queyrat, and Hey Groves). The reaction to antisyphilitic remedies, including salvarsan, is startling in its unevenness. In Schulmann and Weissmann's, Perussia's, Pollitzer's, and Clark's cases, above described, the results were extremely satisfactory, while in others (Giffen, Cases 1 and 3, Hartwell, French) it produced no amelioration. Other cases described, with enlarged spleen, positive W.R., and chlorotic anæmia, have been uninfluenced by salvarsan and other remedies, and we must search for some factor which enables us to explain why one can be cured and the other not. Some enlarged syphilitic testicles can only be cured by excision and the cerebral gumma is not always amenable to specific treatment.

TUBERCULOSIS.

Morbid anatomy teaches us that tuberculosis of the spleen is extremely common as a secondary feature. An enlarged spleen is frequently met with in general glandular tuberculosis, but for the most part it causes no symptoms of splenic disease. Primary tuberculosis of the spleen is rare, but from the reported cases not quite so rare as the syphilitic. Let us examine the evidence for the tuberculous origin of these spleens. Tuberculosis is such a widespread disease that the mere presence of what look like tubercles of any size whatever is not evidence of the causation by tuberculosis of a disorder of this organ. During life the symptoms should point to the spleen being the cause; we should attempt, having proved the spleen to be tuberculous at the operation or post mortem, to fulfil Koch's postulates by ascertaining if the disease from which the patient suffered agreed with what we know in general about primary tuberculosis of the spleen.

I regret to say that, as with syphilis, many authors show some failure to recognise what should and what should not constitute an anatomical diagnosis of

THE

CHRONIC INFLAMMATORY DISEASES OF THE SPLEEN.

Delivered at the London Hospital Medical College

BY ALEXANDER GEORGE GIBSON,
M.D., F.R.C.P. LOND.,
HONORARY PHYSICIAN TO THE RADCLIFFE INFIRMARY AND COUNTY HOSPITAL, OXFORD; LECTURER IN MORBID ANATOMY IN THE UNIVERSITY.

THE chronic inflammatory diseases of the spleen have engaged my attention for several years; our knowledge of the subject is still small and the greater part has still to be discovered or confirmed. I shall limit this review to those affections that are caused by invasion of the spleen by an organism, whether such invasion is indicated by the discovery of the actual organism, by the clinical aspect, or by the fact that the lesion in the spleen, being inflammatory, admits of this view as the most likely ætiology. It is necessary first to allude to certain functions of the spleen in so far as they may be altered by splenic disease, and secondly to mention certain general changes consequent upon splenic inflammation.

The spleen is, first, the main lymph gland of the abdomen, and the lymphatics of the capsule communicate directly with the peritoneal cavity. Secondly, by virtue of its muscular fibres it is the sole remaining lymph heart of the mammalian body. Thirdly, it is one of the organs where effete red cells are destroyed. These functions, as we well know, may be taken over by other organs on extirpation of the spleen, a procedure that produces no serious ill-effect and merely causes the white cells, in particular the mononuclear count, to be in excess for a variable time. Being a lymph gland it naturally supplies certain cells to the blood, chiefly the mononuclear. In embryonic life it produces nucleated red cells and probably acts like the normal red marrow; in various conditions we see a tendency for this reversion to an embryonic function. The spleen becomes infected in three ways: first, as the result of a general blood infection which subsequently may become restricted to the spleen, as in syphilis and tuberculosis; secondly, because the spleen in destroying blood cells comes into fuller contact with the organism, as in malaria and kala-azar; and thirdly, being the largest lymphatic gland in the abdomen, it may be the point of attack in any gastro-intestinal infection.

LOCAL EFFECTS OF INFLAMMATION ON THE SPLEEN.

Apart from abscess and local conditions such as caseation and gummata, splenic inflammations may conveniently be divided into the acute and chronic forms. In the acute form the spleen is enlarged, its capsule stretched, and it is a flabby organ at the post mortem, though in the living body by reason of the tension of the blood it is probably firm to the touch. The Malpighian bodies are seen with difficulty and the whole of the pulp can be expressed as a reddish opaque fluid which contains red and white cells intimately mixed; this picture is what we term the septic spleen. In the chronic form of inflammation the general effect is to cause a hyperplasia and subsequently a reduction in the lymphoid elements, leading to an obscuration of the normal distinction between Malpighian body and pulp. One form, the hyperplasic, shows intense catarrh and filling up of the sinuses of the spleen with cellular elements. In the atrophic form the Malpighian bodies atrophy, sometimes showing mere shrinkage, sometimes being replaced by endothelial cells, beginning in the centre. In addition there is much deposition of fibrous tissue rendering the splenic reticulum much coarser than normal, increasing considerably the thickness of the trabeculæ and sometimes the capsule. Along with these changes, which are constant, others occur in variable amount:—

1. Congestion or stasis in the pulp; the lacunæ in these parts are overfilled with blood as compared with other parts or with the normal spleen.
2. True hæmorrhage occurs in the trabeculæ, if they are thick, in the circumferential parts, giving rise later to the pinhead areas of absorbing hæmorrhage or pigmented scars that may be detected in many chronically inflamed organs.
3. Endothelial proliferation in the sinuses, which may show various types of cells.
4. Sclerotic lesions of the vessels—this is especially true of the central artery to the Malpighian body, where the thickening affects the whole substance of the walls and is mostly of the hyaline type, similar to that seen in other organs such as the kidney.
5. Endophlebitis of the veins communicating directly with the splenic pulp, with the formation of thrombi, which may become detached.
6. Infarcts, as to the mechanism of whose formation there is still some doubt. The fact that they are frequently seen in those spleens in which the trabeculæ show most hæmorrhages might associate this process with it. It is certain that it is a local splenic affection and not produced by emboli formed elsewhere.
7. Amyloid change occurs frequently and is confirmatory of the infective origin of such inflammatory affections as cannot be referred to a known specific cause.
8. Embolism of the splenic vein with or without the circulation of non-particulate toxin sooner or later produces gross changes in the portal area of the liver leading to destruction of liver tissue and fibrosis. Infarction from this cause has not to my knowledge been described, but I hope soon to publish experimental proof of its origin in this way.

All these changes in varying amounts are common to chronic splenitis of whatever causation. If the disease be more active we see hyperplasia and enlargement; if it be late and quiescent we find fibrosis and atrophy. Post mortem many fibrotic spleens are met with which have had active chronic disease at same time.

BODILY EFFECTS OF CHRONIC INFLAMMATORY LESIONS OF THE SPLEEN.

It is extraordinary to what extent the spleen may be enlarged and inflamed without producing serious constitutional effects, especially in some of the familial types such as splenomegaly with acholuric jaundice. It can only be explained by supposing that the subject of such splenomegaly having grown up with his lesion, does not consider the sense of ill-health or local discomfort abnormal.

1. The first general effect is a sense of fullness; weight, oppression, or pain in the side from the presence of a tumour.
2. Anorexia, the effects of toxæmia with or without fever, seldom of a high grade.
3. If a chronic inflammation of the spleen begin early enough or is sufficiently intense it will have a marked effect in retarding growth and development. Such effects have been described by Gilbert and Fournier and by Frederick Taylor.[1] Children show stunted growth, osseous changes, clubbed fingers, pigmentation of the skin, fissuring of the tongue, and other evidences of malnutrition. Several cases are described with epileptic attacks. In adults there may be considerable atrophy in various organs with marked pigmentary changes in the skin, general or patchy. It is no doubt possible that these changes may occasionally be the result of congenital syphilis with splenomegaly, but cases are now sufficiently numerous in the absence of signs of syphilis to establish their origin from causes associated with the splenomegaly.
4. Anæmia. All forms of splenic inflammation tend to the destruction of blood elements, but in varying degrees, so that the term splenic anæmia for what is probably a specific infection of the spleen is a poor name. Splenic inflammation produces most frequently an anæmia of the chlorotic type. In a proportion of cases there is a marked diminution of white cells without any serious alteration in their relative proportions. Some cases show even an increase in white cells. That changes in the number of white cells are not indicative of any specific infection it is only necessary to mention that the most marked examples of diminution are seen in kala-azar. I have myself watched the gradual onset and disappearance of a chlorotic anæmia with leucopenia and enlargement of the spleen in a lady who had previously been operated upon for tuberculous glands of the neck. It has been suggested that the anæmia may be due to the hæmatemesis that occurs in the so-called splenic anæmia; but this cannot be the full ætiology, as the anæmia

with many specific causes. This would certainly be true of syphilis, in which, apart from the effect of a splenic inflammation, a coexistent hepatitis might cause the jaundice. As regards the subdivision of this group of cases into the acquired (Hayem, Widal) and the congenital (Chauffard, Minkowski) there is no difficulty in presupposing an infective element if the analogy of syphilis be taken into account, and the extremely variable onset of the symptoms. Touching the congenital cases we may recall Beneck and Sabrazés'[32] observation of a suckling who acquired the disease from a wet nurse, who with two children was suffering from it. Considering also the numerous observations of its familial incidence the possibility of an infective cause becomes much stronger. The symptoms of this disease are a long-continued jaundice, sometimes with intervals and often with bouts of pain simulating cholelithiasis. The urine contains no bile. The degree of ill-health is often so little that patients continue to work as normal persons. The splenomegaly is often moderate, but large spleens are more usually met with, especially in the congenital variety. The anæmia is not often or markedly severe; it is of the chlorotic type, with an average red cell count of just over 3 millions. In some of the cases an anæmia of the pernicious type has been recorded (Gilbert,[33] Umber,[34] Burghard and Sutherland,[35] Giffen,[36] and Mosse[37]). The white cells vary, sometimes being increased, sometimes reduced, but they do not invariably show that reduction which is more characteristic of splenic anæmia. An increase of fragility of the red cells described first by Chauffard is seen in a large proportion of cases.

Morbid Anatomy.—The spleen tends to adhere to a definite type which is an argument in the uniformity of causation. The organ is firm and dark red to plum-coloured with little or no perisplenitis and few adhesions to other organs. On section the surface is very dark red and both Malphigian bodies and trabeculæ can be made out. Along the course of the trabeculæ, which show but little thickening, there may be seen hæmorrhages and brown or buff-coloured points the site of previous hæmorrhages. I have seen small infarcts in some; microscopically there is a moderate degree of fibrosis, engorgement of the sinuses with red cells, thickening of and hæmorrhage into the trabeculæ.

Ætiology.—With regard to the causation of this type of splenomegaly the only evidence I have leads me to think that it is due to a streptothrix organism.[38] In one case recently published I was able from the spleen pulp to isolate a streptothrix of the actinomyces type which is mildly pathogenetic to monkeys.[39] Further experiments with monkeys now in progress lead me to a greater assurance on this point. Intraperitoneal injection of a culture produces a prolonged period of general seediness with or without an enlarged spleen from which the animals may or may not recover. The human spleen from which this culture was originally obtained showed pigmented points in the trabeculæ in which were threads morphologically similar to those of a streptothrix. Here I may say that in previous writings where I have given the impression that Wheal and Chown's stain is specific for these threads, I have been wrong. This stain shows up iron pigment well and therefore all fibres thus impregnated, tissue threads included, are stained black; a diligent search, however, in the pigmented points reveals septate threads with segmenting ends and such can be seen in sections stained by hæmatoxylin alone. My view is that the reason for the hæmorrhage in the first instance is the presence of the organism and therefore in many healed lesions the organism must necessarily be equally impregnated with the tissue. It also bears on the point to say that the culture obtained from my case came from one of the pigmented points, and that all those from the pulp were sterile, as also were many from the former. It will be necessary to obtain positive cultural results in more cases before any more certainty can be expressed. The therapeutic effects of splenectomy in these cases are very satisfactory, and the operation should be undertaken in all cases where the disease produces a serious interference with ordinary life. Many cases, however, are not seriously ill, and to urge the necessity for operation is not desirable.

Splenic Anæmia.

The conditions included under this term may naturally comprise cases of a varied causation. As a definition of a disease it is bad and must ultimately disappear as our ætiological groups become manifest. But in shaping our knowledge it has served a very useful purpose in concentrating thought on this type; for though it is undoubted that many cases of known ætiology—e.g., from syphilis, tuberculosis, or malaria—might present the symptoms and signs of splenic anæmia, yet there is a unanimity of clinical opinion that there are a large number of cases with these symptoms of anæmia and splenomegaly that do not fall into any of the groups with a known cause. If I have been right in the manner of presenting the general symptoms of splenic inflammatory disease then we must assume that many infections located in the spleen may be severe enough to produce anæmia. It is only necessary to mention that kala-azar, malaria, and Egyptian splenomegaly,[40] the two former being specific in their ætiology, all produce marked anæmia and an enlarged spleen. The chronic septic splenomegaly, a febrile illness of many weeks with enlarged spleen, anæmia, and leucopenia, recently described by Sir John Rose Bradford,[41] is another instance. But when all these varieties depending on a cause specific to each have been eliminated there remains a group of cases that are neither syphilis nor tuberculosis and do not belong to any other known specific group. Such cases are very chronic, unless in children, and, as Banti long ago pointed out, they ultimately lead to cirrhosis of the liver and ascites.

Morbid Anatomy.—The size of the organ may be moderate or large. There is not much perisplenitis and that in patches only. The cut surface shows a marked fibrosis affecting both pulp and trabeculæ which may be very thick. The Malphigian bodies are reduced. The most constant feature, however, is the large number of pigmented points along the trabeculæ which, if seen in the early stage, are hæmorrhages. The whole surface may show a reticular arrangement of these pigmented fibres, so extensive has been this hæmorrhage. This appearance, as has been mentioned before, is not confined to one or two groups of splenic inflammation; but my experience teaches me that it is more marked in this than in other types if we except certain of the leukæmias.

Ætiology.—In three cases I have been able to examine by the kindness of my London colleagues I have obtained positive bacteriological results from the spleen in two. The cases were as follows:—

1. Male, aged 30, under the care of Dr. Batty Shaw in University College Hospital, with a history of repeated hæmatemesis, from the last of which he did not recover. The W.R. was negative. Cultures were made from the spleen and I only found out later that it had not been removed surgically as had been intended; it showed, however, no sepsis. The organisms from post-mortem spleens are usually very abundant and of the *B. coli* type; in this spleen, however, two-thirds of the culture-tubes were sterile, the others showed a Gram-negative cladothrix type of organism with punctate thickening, growing very delicately on agar. One of these cultures was kept going for several months, but ultimately died out. On agar slope it showed five separate dew-drop colonies which, by transmitted light, were slightly opaque. It was non-pathogenetic to guinea-pigs and mice. The length of time that elapsed before a bacteriological examination largely invalidates the findings as evidence of the causation in this case, but the fact of finding a cladothrix of such cultural character is unusual if it were a post-mortem contamination from the bowel.

2. A male, aged 34, admitted to this hospital under Dr. Robert Hutchison for indigestion, repeated hæmatemesis, and an enlarged spleen. Mr. A. J. Walton removed the spleen and had it sent to me direct for culture. There was a history of enteric during the South African War. The anæmia was of a pronounced secondary type, and the W.R. negative. The spleen showed slight thickenings of the capsule where there had been adhesions. The cross section was a dull red with a firm pulp. Malphigian bodies and trabeculæ could be seen, and the latter appeared not to be thickened. In all sections could be seen pin-head areas of hæmorrhage in connexion with trabeculæ. Microscopically there was general cellular hyperplasia and increase of fibrous tissue. The trabeculæ showed hæmorrhages and the Malphigian bodies were diffuse. No portions infiltrated with iron pigment were seen. Culture of the hæmorrhagic areas proved to be positive in 10 out of 15, the remaining 5 being sterile. All the cultures tested after several sub-cultures were the same, a Gram-negative non-sporing bacillus very variable in length up to four times the diameter of a red cell and uniformly thick. The longer forms were bent or curved and some showed septa and dot-like refractive granules. The ends were rounded. Some of the smaller bacilli were actively motile. They tended to adhere in clumps from the edges of which long forms are seen projecting. True branching was not observed. On agar it grew as a thin whitish opales-

When an infection of the spleen is capable of proof by demonstration of the bacterial cause let us admit for purposes of science only those cases thus proven, allowing the other cases as doubtful.

I propose, therefore, in dealing with the specific infections of the spleen to be severely critical as to what shall and what shall not be included in the respective groups.

SYPHILITIC SPLENITIS.

Syphilis as an acute disease causes an enlargement of the spleen in the secondary stage, especially in congenital cases, and there is a consensus of clinical opinion, which I do not dispute, that splenomegaly may be present as a principal feature in the tertiary stage. When we come to examine the evidence for this in the recorded cases, numbers must be rejected as being uncertain, because the proof of their syphilitic origin rests on too slender evidence. Upon what evidence may the nature of the infecting spirochæte be reliably determined? The conditions are as follows:—

1. The presence of an inflammatory lesion in the spleen with the features of syphilitic inflammation in which the *Spirochæta pallida* has been found or transmitted to animals. This is I believe fundamental if we are even to acquire any accurate knowledge of the clinical effects of the syphilitic spleen. Such splenomegaly being tertiary, it will be all the more difficult to stain spirochætes, and Prof. H. M. Turnbull assures me it requires very prolonged search by our present methods. Nevertheless the spirochæte has been reported in such spleens, and it may be hoped that improved methods will allow of their more frequent discovery.

2. Secondary criteria not in themselves proof, but giving a strong probability of syphilitic origin. These are (*a*) a family or previous history of syphilis; (*b*) external or internal evidence of syphilis in the body, including a positive reaction to Wassermann's test. In the absence of other evidence a positive Wassermann test is no proof that an enlarged spleen is the result of syphilis. Such a conjunction may be excellent clinical ground for applying full anti-syphilitic treatment, but while syphilis is so prevalent it is no sure argument for a syphilitic origin; (*c*) the reaction to treatment. Other diseases react well to all the remedies employed in syphilis; therefore the evidence derived from this source cannot but be doubtful.

Morbid Anatomy.—Variable estimates have been reported of the number of syphilitics affected with enlargement of the spleen. It is more frequent in congenital cases in which the proportion showing splenic enlargement has been reported by Hasland[5] as 36·4 per cent. and by Costens[6] as 48·55 per cent. In acquired syphilis it has been variously estimated from 2 to 36 per cent., but the lower figure is probably truer than the higher. Apart from the acute infectious type of spleen that has been described in the secondary stage, two forms may be described, according to the presence or absence of stasis in the portal vein resulting from thrombosis or obstruction in the portal vein or its branches. This form gives rise to enlargement mainly from dilatation of the splenic venules, catarrh of the sinuses and deposition of fibrous tissue. The second form is a true splenitis of the chronic type, with marked increase of fibrous tissue especially of the capsule which may be raised into small buttons or knobs. The Malpighian bodies are atrophied and the sinuses replaced by thick-walled lacunæ, showing catarrhal changes. End-arteritis is so constantly present in all forms of splenitis that it forms no distinctive feature of this type. There is little to distinguish the syphilitic fibrosis from other types, unless it be perisplenitis. Miliary gummata have been described as in syphilitic hepatitis. True gummata have also been described, but Prof. Turnbull assures me that he has never yet seen a gumma of the spleen in the London Hospital. A similar reference to its rarity is made by Coutts in his Hunterian Lectures, 1896. Hasland made 151 autopsies in syphilis in which the spleen was affected, but found no gumma. In the absence of bacilli some tuberculomas might easily be mistaken for gummata. In considering the reported cases of primary splenomegaly from syphilis the majority of these are not indubitably syphilis, so that the clinical picture must be held in some uncertainty. I have felt it my duty to review all the cases available to me, and have found altogether 25 cases reported as primary syphilitic splenomegaly, but of these only two are of first importance in having adequate proof of syphilitic origin. These two cases have been reported by Giffen[7] from the Mayo Clinic, and both were found to have *Spirochæta pallida* in the walls of the arterioles.

1. Giffen. Case 1.—Female, aged 40, with a history of an enlarged spleen since an attack of typhoid fever 12 years previously. One year before she had an abscess of the chest wall which had discharged dead bone and had not properly healed. Four weeks previously she had had abdominal pains followed by slight jaundice. The W.R. was four plus. There had been no hæmorrhage. The spleen was very much enlarged and no effect was produced with antisyphilitic remedies. The blood count showed a moderately severe chlorotic anæmia, R.B.C. 2,950,000, W.B.C. 6650, Hb 48 per cent., colour index 0·6, and a differential count that was not abnormal. The spleen, 12 in. long by 7 in. broad, adherent to the neighbouring organs, was removed by operation. The patient made a good recovery and one year after her blood count was: R.B.C. 3,552,000, W.B.C. 11,000, Hb 80 per cent., colour index 1·02, differential count normal. The spleen weighed 900 g.; it was normal in contour, the external surface being slightly nodular and showing considerable perisplenitis; on section it was firm, tough, and very dark-coloured; microscopically there was diffuse fibrosis with marked arterio-sclerosis, the adventitia of some of the arteries being thickened and amounting to typical gummata. In the vessel walls *Spirochæta pallida* was found.

2. Giffen. Case 3.—Male, aged 35, with a history of syphilis at 21. He had had three positive W.R. tests during the previous two years, but at the time of examination it was negative. There were moderate splenomegaly, slight anæmia, and recurrent hæmatemesis. He had had long antisyphilitic treatment with partial relief only. In his previous history he had had jaundice for two months, six years previously, and about that time he had an ulcer of the right shin. The liver and spleen had been enlarged for two years previously. There had been recurrent hæmatemesis. He complained of headache and had had nodules over the frontal region. The spleen, removed by operation, was five times the normal size, showing intense general fibrosis, some pigment, arterio-sclerosis, and a typical small gumma near a vessel. A few spirochætes were found. The liver was deeply fissured and small. The blood count nine days before operation showed R.B.C. 4,240,000, W.B.C. 4900, Hb 85 per cent. The recovery was uneventful.

Coming now to those reported cases whose syphilitic causation is probable only: one group of these showed a marked improvement under salvarsan or neosalvarsan.

3. Schulmann and Weissmann.—Male, aged 40, with congenital syphilis and erythema—R.B.C. 12,000,000. Under a course of neosalvarsan the R.B.C. became 6,000,000. The white cells were 8000, and remained unchanged.

4. W. Schmidt.[8]—Female, aged 14, whose mother had tabes, had two abortions immediately before the patient's birth, and suffered from an enlarged spleen, anæmia, enlarged liver and glands of the neck; R.B.C. 4,800,000, W.B.C. 3200, Hb 84 per cent. The Wassermann reaction (W.R.) was positive. There was considerable lessening in the tumour and betterment of the general conditions by a subcutaneous injection of salvarsan.

5. Perussia.[9]—Female, aged 30, with a history of two miscarriages, repeated metrorrhagia leading to very bad anæmia, Hb 22 per cent., R.B.C. 1,090,000, W.B.C. 4800, C.I. 0·6. There was enlarged liver, vomiting, diarrhœa, and mild fever; W.R. negative. After a course of salvarsan there was marked diminution of the spleen, complete restoration to normal health, and no objective anæmia.

6. Pollitzer.[10]—Female, aged 13, having had splenomegaly since the age of 2, and recurrent jaundice. The fragility of the corpuscles was increased (0·54 per cent.). The W.R. at the age of 11 was positive. After an injection of salvarsan the jaundice disappeared for three months.

7. Clark.[11]—*A patient with the picture of splenic anæmia* and Banti's disease and negative W.R., cured by antisyphilitic treatment.

8. Anderson.[12]—A man, aged 33, with attacks of diarrhœa for six years and persistent jaundice the previous year. There were old healed ulcers on the right leg below the knee; W.R. positive. There was jaundice, enlarged spleen, œdema, and anæmia (R.B.C. 4,800,000, W.B.C. 4000, Hb 70 per cent.). Cure was effected by hydrargyrum c̄. creta, and later by repeated salvarsan injections.

9. Vaillardi.[13]—A case reported as syphilis improved markedly under salvarsan, but as the patient had had severe

their preference for a particular soil, but the reaction of the local tissues and the general protective mechanism of the body do not alter, whatever may be the type of infecting agent.

The two great principles, therefore, that underlie the treatment of all acute inflammatory conditions are: (1) the relief of tension and its maintenance; and (2) absolute rest.

A third principle of scarcely less importance is the avoidance as far as possible of super-infection, meaning by this that during any necessary operation or post-operative dressings the strictest asepsis must be maintained. Further, in the treatment of the wound itself, much assistance can be derived from the use of chemical agents to promote the separation of dead tissue or to stimulate the natural reaction of the healthy tissue, while the bacteriologist has supplied powerful means to increase the resistance of the blood. It is not my intention here to deal with the treatment of sepsis resulting from a wound of the soft tissues or bones. The main effort in any injury is to avoid sepsis by an early excision of the damaged tissues, followed by closure of the wound and efficient splinting; but should infection occur there is no difference between its treatment and that of other acute inflammations.

Acute Suppuration of the Soft Tissues of the Limbs.

In every case, when first seen, the affected limb should be immobilised at once, and immobilisation can only be secured by an appropriate splint. While for the fingers a straight forearm or internal angular splint may suffice in any spreading infection, a Thomas's arm or leg splint is the most satisfactory. From the patient's view-point the application of a large splint for what appears perhaps a trivial lesion may seem unnecessary; but the apparently trivial lesion has immense possibilities for danger; fingers, limbs, lives have been lost through neglect of this precaution in the early stages. In the majority of cases it will be found that the spread of infection can be controlled by this means. The question of when and where to make an incision in an inflamed area for the relief of tension is sometimes difficult. If by splinting the spread is controlled and becoming localised, my impression is that it is better to wait for the formation of pus before incising. If the inflammation is localising itself the main danger has passed, and with the limb at rest further spread is unlikely. The formation of pus is a healthy sign that the tissues are reacting strongly. When it has formed an incision of the same length as the abscess cavity is made, care being taken that the whole cavity is exposed, but no fresh tissue planes are opened up. The size of the cavity may demand more than one incision. The splint should not be discarded until all signs of sepsis have disappeared and the wound has commenced to heal.

In those cases of acute septic inflammation of a limb, when in spite of immobilisation there is no effort to arrest the spread and no indication of suppuration, one or more incisions over the areas of greatest tension are of the utmost value. Such incisions should open the skin, subcutaneous tissue and deep fascia, and should correspond closely with the areas of maximum tension, thus avoiding laying open fresh tissues to infection. Provided the selection of the site has been carefully made, the value of an opening to relieve the tension and to give the tissues a greater chance of reacting is very great, and may be extended in certain cases to the true forms of non-suppurative inflammation. All such incisions almost invariably become septic and are dealt with in the usual way. There is the occasional case when, in spite of every precaution, the infection passes beyond the limb into the general circulation, owing apparently to an entire failure of tissue reaction. It is here that the bacteriologist may save life and limb, though this remark by no means suggests that his services should be neglected in the less severe cases.

Acute Suppurative Osteomyelitis.

The primary object in all cases of acute bone inflammation must be to lay open at once the whole of the infected area in order to relieve tension. In every case the bone cavity must be opened. Often it is difficult to judge to what extent this should be done. If there is subperiosteal pus the extent of the opening into the medullary cavity should correspond with that of the stripping up of the periosteum. In those cases when the pus is confined to the medullary cavity—the most acute and fortunately more uncommon type of case—a wide opening should be made in the bone. My impression is that drastic treatment is safer in all cases, since even if healthy medulla is opened and becomes infected, this involves less risk than does an inadequate opening, while a line of least resistance is provided. Afterwards the limb must be completely immobilised by means of a Thomas's splint and cross-strapping, the strapping being arranged so that the dressings may be carried out with the minimum disturbance and pain, and the whole limb being suspended from an overhead frame. In these cases intermittent or continuous irrigation is valuable, chiefly because thereby painful dressings can be avoided. A fairly wide experience of these cases has led me to take a somewhat pessimistic view of them. If the immediate dangers are successfully overcome the subsequent prolonged and unavoidable sepsis is a big strain on the patient. To avoid this strain some have advocated an immediate subperiosteal resection of the infected area of diaphysis with almost complete closure of the wound, followed by the application of extension to the limb in order to maintain its length until the new bone has formed. My experience of this method is too limited to allow me to express an opinion on it, either for or against, but I believe it to be based on sound surgical principles. Sometimes, when faced with a severe case, I have been in doubt whether to perform an immediate amputation. After much hesitation, and finally deciding against it, I have in the end sincerely regretted my decision. The idea of amputation is repellent and not likely to appeal to anyone as a primary measure; on the other hand, amputation in such cases can be considered unjustifiable only on the guarantee of thorough relief of tension and true immobilisation. There is yet one more variety of diaphysitis in which, owing to the position of the epiphysis, a joint is directly involved. Here the conditions are the same as in an acute suppurative arthritis, and are to be treated as such (vide infra). The issue of such a case is, however, complicated by the inability to remove the focus of infection. Suppuration continues and a sinus is inevitable until the necrosed tissue has separated. Although the ultimate outlook for the joint is doubtful, as soon as the acute stage has passed our chief object must be to encourage movement.

Acute Suppurative Arthritis.

While it is not possible to correlate in one short paragraph the pros and cons of treatment in joint suppuration, a short reference is necessary because, at first sight, it appears as if the principle of immobilisation requires modification. The essential function of a joint is to move, and this fact must never be lost sight of. Hence treatment must satisfy two apparently opposed demands, immobilisation of the joint and preservation of this essential function of movement. A joint is immobilised not so much by keeping the limb at rest as by a separation of its articular surfaces; if it is possible to maintain this there is no reason why early active movements of the infected joint may not be carried out with a view to hindering the formation of adhesions in and around the joint. Extension, then, is our main method of immobilising a joint, and this should be powerful and continuous until the active suppuration has passed. When considering the means of relieving tension in a joint, we must bear in mind the possibility of an attempt on the part of the synovial membrane tuberculosis of the spleen. Some cases are reported as such merely on the naked-eye diagnosis, whether the lesions be of the miliary or caseous type. I admit a high degree of probability and accuracy in such opinions, but they cannot be deemed to approach the accuracy demanded from a scientific test. Some authors fail to give a report of the histology and a large number omit any mention of a search for tubercle bacilli. As in other situations—tuberculosis of the skin for instance—it may require a prolonged search to find tubercle bacilli or they may never be found in what is a clear case. For the tuberculous origin to be adequately proved we should demand in an enlarged spleen the presence of tubercle bacilli in lesions which should suggest this origin, and no serious or general tuberculosis in other organs. Moreover, it is necessary to stipulate that there should be no serious disease in other organs masking the splenic symptoms. One case, for instance, reported as tuberculosis of the spleen, had infective endocarditis and infarcts in the spleen. I have also other evidence that need not now be detailed, that some splenic infections show a lessened resistance to tuberculosis, and a tendency to stir into activity some old lesion. As regards the recorded cases of primary tuberculosis of the spleen we have the very complete account of those recorded up to 1912, by Winternitz.[25] Some of these 51 cases are not sufficiently proved to be included in this summary. There remain, however, 17 clear cases of primary tuberculosis of the spleen, in which tubercle bacilli had been found. In subsequent years I have been able to discover four others reported by Bianchi,[26] Schubert and Geigel,[27] de Montmollin,[28] and P. Albrecht.[29] It will not be necessary to record the individual cases (see References). A summary will serve to make clear their anatomical and clinical characteristics.

Morbid anatomy.—The tubercle bacillus may cause in the spleen both acute and chronic inflammations. (1) In the acute variety the spleen is described as simulating the typhoid spleen with or without the presence of naked-eye tubercles. (2) Disseminated miliary, caseous, or endothelioid tubercles with varying fibrosis of the pulp and some slight fibrosis of the capsule, upon which may be seen minute scars of old healed miliary or even caseous tubercles. In the early stages of this type hæmorrhages are present. (3) A third type must be added to these—namely, chronic generalised fibrosis with red or pale pulp and a few scattered points, the remains of minute caseating areas, suggesting a tuberculous origin. This is the condition in a spleen removed in the London Hospital from one of Lord Dawson's cases in 1912. No tubercle bacilli could be seen in stained sections, but portions of the pulp were infective to a guinea-pig. A similar spleen again positive only to a guinea-pig experiment is recorded by Auché.[30] The congestion in all these forms may be very severe, the sinuses being distended with blood. True hæmorrhages may occur, especially in the trabeculæ. The Malpighian bodies, which are the site of the majority of tubercles, may either show little change or the centre may gradually be replaced by epithelioid cells included in which may be a giant cell. Some may show caseation and in the more chronic cases the Malpighian bodies are completely replaced by tuberculous structures. The other forms of splenomegaly in tuberculous disease—e.g., amyloid—are secondary to other lesions and therefore do not concern us.

The symptoms of tuberculous splenomegaly may be general and local. In about 25 per cent. of cases there is fever, sometimes in attacks and sometimes as a marked feature. Sweating and collapse is mentioned, and very constantly loss of weight, weakness, and great lassitude. As regards local symptoms there is pain and a sensation of tumour and weight in the left side. The pain may vary in its incidence with positions and movements of the body, or may come on only during digestion. The proximity to the diaphragm may cause pain in respiration. The majority of cases are very chronic, but short illnesses terminated by death have been recorded. There are 15 clear cases in the literature that have been operated upon, with nine cures. The disease is not strictly primary in the spleen; other organs show signs of tuberculosis. Thus of Winternitz's cases nearly half showed pulmonary changes, and five had enlargement of other glands. Other clinical features have been an enlarged liver with cirrhosis (Sotti[31]), ascites, caries of the spine, meningitis, and intestinal ulceration. The features in the blood are either absent altogether or very moderate. In nine cases in which tubercle bacilli have been found in the spleen, the condition of whose blood is mentioned, six were normal and five have counts with a moderate degree of anæmia of the chlorotic type. The lowest red count is 3,200,000 and the lowest white count is 2500, the average white count being 5000. The lowest hæmoglobin figure is 50 per cent. The degree of anæmia is therefore slight and has not been a marked feature of any case.

It is current opinion following on Winternitz's critical review that polycythæmia is one of the characteristics of a tuberculous splenomegaly. But in eliminating from our list of cases those whose tuberculous origin is not adequately proved no case shows an abnormally high blood count. Of the doubtful cases, that of Moutard-Martin and Lefas, whose blood showed 8,200,000 R.B.C. and 31,428 W.B.C., there was naked-eye evidence of tuberculosis in many other organs than the spleen, and even admitting the tuberculous origin the relation between tuberculosis of the spleen and the polycythæmia is not clear. In Carminotti's case there was a much scarred spleen, but no other evidence of tuberculosis, and caries of the spine. Here the counts were R.B.C. 7,000,000, W.B.C. 6000. The other four cases recorded by Winternitz have a R.B.C. of 6,000,000. On these grounds we cannot yet admit that polycythæmia is proven as an association with a tuberculous splenomegaly. On general grounds that have previously been discussed a polycythæmia may be expected if there be obstruction in the portal vein; such, however, cannot be used in any case as an argument for a tuberculous origin of a chronic splenitis. When tuberculosis affects the thorax as well as the spleen there are other possibilities for a mild polycythæmia.

Implication of the liver is not uncommon. Of Winternitz's 17 positive cases tubercles were present in 10 and there was atrophic cirrhosis in one. Sotti describes the liver changes in these cases as frequent. The common anatomical changes are fatty degeneration, necrosis, swelling and thickening of the collagen substance, and sometimes small lymphatic accumulations, and he looks upon interstitial hepatitis as dependent upon changes in the splenic vein. Jaundice as a symptom of tuberculous hepatitis in these cases is rare and I have only found one mention of it, in Winternitz's own case. Hæmatemesis is not recorded in any case, unless we admit that of Paulicek, in which tubercle bacilli were not found. This case had a hæmatemesis at six years when the illness commenced. Glands are mentioned as enlarged in four cases and the lungs were affected in six cases.

Splenitis from Malaria and Kala-Azar.

It would not be in keeping with my purpose to discuss in similar detail other types of specific inflammations of the spleen whose ætiology is uncertain. The two best-known types are those due to malaria and kala-azar. In the former, symptoms specially related to the spleen are not frequent, but when they exist splenectomy is a possible and very successful remedy. In kala-azar with a moderate degree of anæmia of the chlorotic type there is an unusual diminution in the number of leucocytes of the blood, sometimes to below 1000 per c.mm.

OTHER CHRONIC INFLAMMATIONS OF THE SPLEEN.

We have hitherto followed an ætiological classification, and there still remain those types for which we have no certain cause. From what has been said on the general symptoms associated with chronic splenitis it will be apparent that if we attempt a too rigid subdivision from the symptoms and signs alone we shall be hindering a proper knowledge of ætiology. Nevertheless, a provisional clinical classification is necessary for practical purposes, and if we are aware of its limitations no error will ensue. Moreover, even on our purely clinical classifications we may be able to separate the cases into their ætiological types. When classification is not based on ætiology we run the risk of undue complication. In those types we further consider I propose to adhere to clinical views. Such groups of cases are: (1) Acholuric Jaundice, including the congenital and acquired types; (2) Splenic Anæmia (so called); (3) Gaucher's splenomegaly; (4) Egyptian splenomegaly; (5) Hodgkin's disease (splenic type). It will be sufficient, however, to notice the first two.

Acholuric Jaundice.

There would be a consensus of opinion amongst clinicians that a majority of the cases described under this heading probably owe their origin to a single cause or a group of nearly allied causes. From the general account of splenic inflammation it will be obvious that such a group of symptoms is possible necessary, and these should be done as soon as the signs point to a further collection of pus. For routine treatment this method is necessarily somewhat difficult besides being rather uncertain, but in bilateral empyemata it is of great value. The method of opening and completely emptying the abscess cavity is not only quicker and more certain but also safer, provided that in a case presenting grave constitutional symptoms a preliminary relief of tension by aspiration renders the condition suitable for an operative procedure. After emptying the cavity of pus the question of completely closing the chest wall again must be decided on the merits of each individual case. If, however, signs supervene of further suppuration and rise of tension aspiration is performed or the incision re-opened.

The generally accepted method, therefore, of opening an empyema by resection of a portion of a rib and maintaining the opening by the insertion of a tube is probably the simplest, provided that in all cases the opening is made at the lowest limit of the abscess cavity. The tube, however, here as elsewhere, provides a very sure path for the entrance of fresh organisms. Consequently if this method is employed every precaution must be taken to prevent super-infection. This purpose is best attained first by using a long tube, whose free end is carried into a vessel containing some antiseptic; secondly, by fixing a Carrel tube around the tube entering the chest wall (Dean). With this arrangement the long tube may be removed after 48 hours, intermittent irrigation of the wound being continued till healing has commenced.

In the early stages of suppuration in the chest, by arrest of the movements of the diaphragm and chest wall and diminished expansion of the lung, a condition of immobility is brought about. Unless the tension is relieved a paralysis ensues, and if the abscess cavity is then opened and emptied the lung fails to re-expand. It gradually becomes anchored by the formation of dense adhesions which at a later stage, in spite perhaps of recovery of the lung itself, will prevent its expansion. What, therefore, as in the abdomen is primarily a physiological action becomes a pathological danger through delay. As soon as tension has been relieved in the chest by liberation of the pus the lung requires some assistance to resume its normal function, which can be best rendered by routine breathing exercises under open-air conditions.

These remarks may invite criticism on the score of lack of originality, and may appear very elementary; my object has not, however, been to put forth any new ideas, but rather to recall to mind and strongly emphasise a few fundamental principles that must be applied to the early treatment of all such conditions of suppuration as may constitute emergencies of daily practice. Whatever the type and situation of a suppurative process, and whatever additional means of treatment may be indicated, a successful issue must depend directly and primarily upon the application of these principles.

Foreign Decorations for War Services.—The King has granted permission to the undermentioned to wear the following decorations, which have been conferred in recognition of valuable services rendered during the war: Legion of Honour—Cross of the Chevalier: Sir W. Arbuthnot Lane, Colonel Sir A. W. Mayo-Robson, Sir StClair Thomson, Sir Sydney Beauchamp, Dr. E. W. Ginner, Dr. H. J. Moore Playfair, Dr. G. C. L. Vintras, and Mr. D. d'Auvergne Wright. Crown of Italy—Cross of Commander: Sir Ernest Hodder-Williams.

Newcastle-on-Tyne and Northern Counties Medical Society.—The first meeting of the session was held in the Royal Victoria Infirmary on Oct. 13th, Mr. S. S. Whillis, the President, being in the chair. The following cases were shown and discussed:—Dr. T. Beattie: Polycythæmia, Myelogenous Leukæmia, Pernicious Anæmia. Dr. Hesley Drummond: Myelitis, Aortic Aneurysm, Disseminated Sclerosis. Dr. D. W. Patterson: Infective Endocarditis, Erythromelalgia, Banti's Disease. Mr. J. W. Leech Mr H. M. Johnston: Cases Illustrating Sarcoma.

ARREST OF AURICULAR FIBRILLATION
BY THE USE OF QUINIDINE.

By ARTHUR W. M. ELLIS, B.A., M.B., M.R.C.P. Lond.,
ASSISTANT DIRECTOR, MEDICAL UNIT, LONDON HOSPITAL;
AND
A. E. CLARK-KENNEDY, M.A., M.R.C.P. Lond.,
FELLOW OF CORPUS CHRISTI COLLEGE, CAMBRIDGE.
(*From the Medical Unit, London Hospital.*)

Introduction.

In the Oliver-Sharpey Lectures for 1921 Sir Thomas Lewis, describing his researches which have done so much to elucidate the mechanism of the production of auricular fibrillation and flutter, pointed out the relatively simple task involved in the treatment of these conditions and foreshadowed its solution. He showed that they depended on circus movement, and that to arrest the process all that was required was to bridge the gap between the head and tail of the circulating wave, a gap which was in point of time only 1/50th of a second and in point of distance only 10 mm. of muscle. While Lewis[1] had been pursuing these researches which led so logically to a method of attack, Frey, working in Kiel, had been investigating empirically the problem of the treatment of auricular fibrillation. In 1914 Wenckebach[2] reported the arrest of auricular fibrillation in a single patient by the use of quinine, g. i. per diem. The effect was only temporary. Stimulated by this observation Frey investigated the effect of quinidine, another alkaloid of cinchona, and in 1918[3] reported his results in the treatment of 22 cases. In 50 per cent. of these satisfactory results were obtained, and a normal cardiac rhythm restored. In a later communication Frey[4] reported his results in 50 cases; in 42 per cent. fibrillation was arrested. He recommended the use of 0·4 g. quinidine by mouth, three times a day, for from six to eight days, beginning with half this dose and increasing gradually to 1·2 g. daily. If cardiac failure is present, compensation should first be restored by the use of digitalis. Then, after suspension of digitalis for one week, quinidine may be given. He states that patients in whom the fibrillation is of recent origin respond best, that a much dilated heart cannot—or can only temporarily—be brought back to its normal rhythm, and that those not responding to digitalis are refractory to quinidine. In several cases the fibrillation was changed by the use of quinidine into auricular flutter.

In two patients under treatment with quinidine Frey noted what he calls temporary cerebral paralysis with sudden cessation of respiration; both cases recovered in the course of a few hours. He considers the effect to be due to a toxic action of the drug in a patient with a drug idiosyncrasy, and advises a preliminary test with small doses in all cases to determine the occurrence of such idiosyncrasies. Schott[5] has shown in experiments on animals that intoxication with quinidine leads to sudden cessation of the respiration. Bergmann[6] has reported the results of treatment in 9 cases of auricular fibrillation; in 6 a normal rhythm was secured, in 2 the fibrillation changed to flutter. Klowitz[7] treated 15 patients, and in only *one* did he succeed in obtaining an arrest of fibrillation. Benjamin and v. Kapff[8] have treated 27 patients. In 18 fibrillation was arrested. In 5 of the 18 successful cases there was a relapse, with return of fibrillation, which again disappeared with further treatment; in 13 of the 18 a temporary tachycardia occurred before the normal rhythm was restored. In one patient the effect appeared unfavourable, and there was increasing failure and death. These authors call attention to the possibility of embolus resulting from the restored auricular contraction, and report one instance of lung embolism and one case of sudden death which they think was probably also due to embolism. They suggest that cent fibre recalling that of paratyphoid B; in broth there was a general turbidity with some deposit later. Gelatin was not liquefied; milk was slowly coagulated; lactose and glucose were fermented with the production of acid and gas. Neutral red lactose broth was changed to fluorescent yellow in 48 hours and became carmine red in ten days. It was aerobic and non-sporing. The organism was pathogenic to rabbits but not to guinea-pigs by intraperitoneal injection. Rabbits by this method of inoculation died in 24 hours to three weeks and there is a well-marked slight peritonitis from which the organism can readily be recovered. Cultures of this organism were kept alive for two years; it then died out despite repeated efforts to revive it. Though this organism has motile elements and has no capsule its nearest kinsfolk appear to be the Friedländer group of organisms.

CONCLUSION.

It is not my purpose to explore the ætiology of the other clinical groups of splenic inflammation, for as you will recognise from what has been said, in most groups our knowledge is still incomplete. I hope it will be clear, however, that it may be possible in any case to get evidence pointing to one or other ætiological group. I have tried to show that splenic disease as such may cause many symptoms and that the ultimate ætiological subdivisions will not necessarily harmonise with the temporary subdivisions based on clinical observation alone. It is only in hospitals like this that opportunities present themselves for the real solution of these problems, and even in this hospital I imagine the removal of a spleen by the surgeon is not an everyday occurrence. Yet if all such spleens could be examined by a bacteriologist of some years' experience and the reports collated, what an array of evidence would be put out for gaining adequate proof of the ætiological causes.

My thanks are due to those gentlemen in this and other hospitals who have given me opportunities that I did not otherwise possess, and who have allowed me to use the clinical notes of their cases.

SOME ASPECTS OF THE TREATMENT OF ACUTE SUPPURATION.

BY F. D. SANER, F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS, GREAT NORTHERN HOSPITAL; SURGEON, EVELINA HOSPITAL FOR SICK CHILDREN.

ALTHOUGH enormous experience was gained in the war as a result of the views put forward by different schools of thought, mainly concerning the details of chemistry and bacteriology of septic wounds, yet I venture to suggest that the fundamental principles of treatment were somewhat obscured, and that the lessons learned then are not now sufficiently applied in dealing with acute septic conditions of civil life. The prominence given to several very attractive but accessory lines of treatment, such as antiseptics, tissue-solvents, serums, artificial hyperæmia, has tended to divert us from consideration of certain of the main principles. In no way is it my purpose to depreciate these adjuncts to treatment, whose great value and importance are generally recognised. But it should be realised that they are only additional means of attack after the main defences have been perfected as far as possible.

"Relief of Tension."

In a different manner the constant use of the word "drainage" has given rise to the idea that drainage is the chief and most important factor in the treatment of suppuration. Further, in the endeavour to secure "drainage" the drainage-tube per se has become an idée fixe. If by a different phrase it is possible to alter the conception of a treatment, I would suggest that the word drainage be eliminated and replaced by "relief of tension." The latter phrase does not suggest to the mind a means of drainage, but rather implies an opening, a line of least resistance in the direction of safety, along which the products of inflammation may escape.

The inflammatory process will take the line of least resistance, whether along lymphatics, blood-vessels, fascial planes, or towards the exterior of the body, and our main object is to make it follow the latter line. In "relief of tension" and in the creation of a "line of least resistance" we thus fulfil a fundamental principle in the treatment of acute septic conditions. The relief must be complete and the line must be maintained, and it is in the maintaining this line that the chief difficulties of technique arise, which will be referred to in their proper sections. Nature, assisted in this way, will create her own drainage, and will gradually cast out the debris of dead tissue which is in itself harmless, except as a suitable soil for the growth of organisms.

Immobilisation.

The second great principle of treatment was enunciated by John Hilton in the following sentence: "Every deviation from the necessary state of rest brings with it, through pain, the admonition that the patient is straying from the condition essential to his restoration." This stands as a profound truth, and in applying it to the treatment of suppuration it is merely necessary to emphasise the word rest or replace it by immobilisation. Only by completely immobilising an inflamed part are the natural agents given a chance to form their barriers against spread of inflammation and to deal locally with its cause. The word immobilisation implies, at any rate, in the case of the limbs, the necessity for an efficient splint. When there is suppuration in the chest or abdomen we can endeavour to assist, or at least refrain, from interference with the natural efforts to maintain the condition of rest. There has been always a tendency to regard the treatment of acute suppuration in different parts of the body from separate view-points. The physiology and pathology are essentially the same whatever tissue is involved, and the principles of treatment do not differ except in the minutiæ of detail. Apparently various pyogenic organisms have

to localise the infection. If any such attempt has taken place its object is defeated by extensive opening of the joint cavity. Therefore, provided true immobilisation of the joint be maintained, it is better to rely on aspiration, or if there is no immediate urgency to deal with fluid or collections of pus by aspiration or incision as occasion arises. In those cases of generalised suppuration of a joint an incision should be made of sufficient extent to allow free evacuation of the pus, and the wound should be closed at once. Further accumulations should, as far as possible, be dealt with by aspiration.

Acute Suppurative Peritonitis.

There is no essential difference between the treatment of acute suppuration in the peritoneal cavity and elsewhere in the body. The same principles hold good, but perhaps are more difficult in their application. While it is a comparatively easy matter to relieve tension in the abdomen, it is a more difficult thing to maintain the relief. At the same time the defensive mechanism of the abdomen against inflammation and its power of localising it is more highly developed than anywhere else in the body. The omentum and peritoneum are wonderfully efficient in the way they attempt to shut off an inflammatory process, and one of our main objects must be to interfere with their work as little as possible. In children this resistance is markedly less than in the adult. The main treatment in any case of abdominal suppuration consists in opening the abdominal cavity. If the diagnosis is uncertain a median or para-median incision is to be made, but if there is reasonable certainty in the diagnosis the incision should be placed directly over the primary source of infection. If an acutely inflamed appendix is palpable, the incision should be immediately over it, otherwise over its usual site in the right iliac fossa, but not towards the mid-line, where the barrier immediately surrounding the inflamed area must necessarily be interfered with. In the case of an abscess in the leg no one would make an incision well to one side of it, thus opening up resisting planes of tissue in order to reach the abscess. The same consideration applies when dealing with the abdomen; we must achieve our purpose at the cost of a minimum disturbance of surrounding healthy and protective tissue. By opening the abdomen, removing the source of inflammation, if possible, and gently removing the pus the immediate tension is relieved. Then it is largely a matter of judgment as to whether the abdomen should be closed and the patient asked to deal with the remainder of the inflammatory process.[1] In all cases where closure is decided upon I would employ interrupted sutures in the peritoneum, aponeurosis, and skin respectively, with a fair interval between them. This allows certain lines of least resistance from the peritoneal cavity; also, should sepsis occur in the wound, individual sutures can be removed.

In cases of spreading or generalised peritonitis the relief of tension must be maintained. The simplest way to accomplish this is to leave the abdominal wall widely open. In children this can be done, but in adults the inevitable protrusion of the gut constitutes a danger and necessitates partial closure. If tubes are inserted it must be on the understanding that their purpose is not "drainage," but an attempt to create at least a temporary track or line of least resistance. Tubes should be left out after 48 hours at most; after this they serve no useful purpose, and are apt to irritate the inflamed intestine and to act as a path for fresh infection from the outside. It is my impression that one incision only should be made in the abdominal wall, and if well placed it will suffice. I believe that stab-punctures elsewhere on the abdomen are not only useless but harmful. They are not of sufficient size to assist in the relief of tension, while they open up new tissue to infection either at once or by the presence of the tube which is inserted. It is better always to make all the paths of least resistance lead to one opening. In cases of pneumococcal peritonitis, if it is possible to diagnose them as such at the time, the abdomen should be closed by interrupted sutures after removal of the free fluid. One is dealing here with a local manifestation of a general infection, and it is of the greatest importance to avoid super-infection. As a rule the involvement of the lungs (perhaps the meninges or joints) becomes manifest after a varying interval of time, and careful watch must be kept for a collection of pus either above or below the diaphragm.

Immobilisation of the abdomen in the strict sense of the word is not possible. Nevertheless, a very great natural effort in this direction is brought into play as soon as any inflammatory process commences in the peritoneum by the arrest of the movements of the abdominal wall and the intestines. This arrest gives the omentum and peritoneum their chance of localising the inflammation and of building their barriers against its spread. The staying of the intestinal movements, although at first physiological and helpful, gradually becomes in the generalised peritonitis the fatal factor by reason of an increasing paralysis and consequent obstruction. In the later stages, also, the muscles of the abdominal wall become paralysed and flaccid. If this stage has been reached before operation the outlook is almost hopeless. The toxæmia has been too prolonged or too powerful. In the earlier stages, however, until tension is relieved the abdominal muscles are kept still and in spasm, and in this condition an incision will more or less maintain the immobility, while the spasm will cease with the relief of tension. Abdominal rigidity implies tension.

As little as possible should the condition of rest of the intestines be disturbed. Drastic purgation, if successful, produces violent movement, while it may induce a paralytic condition through too heavy demands on an already tired mechanism. With tension relieved the intestines will try to carry on their normal functions again, but, as a general rule, they require some assistance in this. Whether pituitary extract has a direct "tonic" action on the intestinal muscle I am unprepared to say, but its value in the acute abdominal conditions alone, or with the aid of enemata is very great. In the case of peritoneal suppuration, with much distension of the intestines, I have found injections of pituitary extract given two hourly from the time the patient is returned to bed, followed by an enema after three or four injections, a most valuable line of treatment. If the first enema produces no result the injections are continued and enemata repeated. This method does not produce violent peristalsis or purgation and it saves the patient much discomfort. Further, it seems to diminish the flatulent distension very markedly, and it is uncommon for patients to complain seriously when thus treated. Flatulence, besides causing much distress and pain, is a danger, as the distension and turmoil of the intestine disturbs the condition of rest; its presence indicates probably some degree of paresis of the gut, and its persistence is liable to increase this.

Acute Suppurative Pleurisy: Empyema.

The same principles of treatment already laid down apply in cases of suppuration in the chest, and their application requires modification only to meet the particular circumstances. In no situation, perhaps, is it so simple to produce and maintain a relief of tension, but in its maintenance the very definite and serious complication of super-infection has to be met. It has been the aim of treatment of recent years to avoid this. If it is possible to give unremitting attention an empyema can be treated by aspiration alone. After the initial aspiration the local and general conditions will immediately improve, and in the exceptional case this improvement will continue without further aspiration being required. As a rule, however, two or more aspirations are that, under quinidine, alteration in both shape and size of the auricular and ventricular waves occur and are accompanied by a prolongation of the P.R. interval.[5] Hoffman [12] has shown that the excitability of the auricle of the excited heart to electrical stimulus is diminished by quinidine, and that stimuli which would normally produce fibrillation of the auricle fail to do so after quinidine has been added to the perfusate. These results indicate an effect on the excitability and conductivity of heart muscle. Lewis has pointed out that the existence of the circulating wave depends on three factors—the length of the path, the refractory period of the heart muscle, and the conductivity. It seems reasonable to suppose that quinidine abolishes fibrillation either by increasing the conductivity or by prolonging the refractory period of heart muscle, with the result that the gap is bridged and circus movement ceases.

---

[1] See H. Wade, Opening Address, Section of Surgery, B.M.A., THE LANCET, August 6th, p. 282.

The restoration of a normal rhythm in five out of seven cases of auricular fibrillation by the use of quinidine is of considerable physiological interest. Its practical value in therapeutics remains to be determined. We would point out from the first that the use of quinidine is not without danger, the risk of embolism being a real one. In our cases the improvement in the general condition was not striking, and much less marked than might have been anticipated, and perhaps little more than might be attributed to the prolonged rest in bed. Certainly no dramatic change in the patient's general condition occurred when normal cardiac rhythm was restored. If the drug is stopped, tendency to relapse seems to be the rule. That quinidine will take a place in the treatment of cardiac disease seems probable, but the nature of its action and the limitations of its therapeutic value remain to be determined.

In conclusion we would express our thanks to Miss Rutherford and Miss Harvey, sisters of the Medical Unit Wards, for the extra trouble they have taken in the supervision of the nursing of these patients.

ACIDOSIS AND TOXIC SYMPTOMS OF SEVERE DIARRHŒA IN INFANCY.

By R. A. GUY, M.D. JOHNS HOPKINS,
MUIRHEAD SCHOLAR, UNIVERSITY OF GLASGOW.

(From Medical Department, Royal Hospital for Sick Children, Glasgow, and Physiology Department, Glasgow University.)

THE toxic symptoms of severe diarrhœa in infancy, especially when associated with an increased pulmonary ventilation without cyanosis, have been shown by Howland and Marriott [1] and by Schloss and Stetson [2] to be accompanied by a state of acidosis.[*] This so-called intoxication was found to be coincident with (1) a decreased tension of the carbon dioxide of the alveolar air; (2) an altered hæmoglobin dissociation curve; (3) an increased tolerance to sodium bicarbonate; and (4) a decreased reserve of available base in the blood plasma.

The administration of alkali has been suggested and used in treatment. In Great Britain but little attention has been paid to this group of cases. Accordingly, at the suggestion of Dr. Leonard Findlay, the present investigation into the alkali reserve of the plasma in cases of diarrhœa in infancy was undertaken.

Methods.

The estimations were made according to the "micro-method" of Van Slyke.[3] [†] The blood was taken by the investigator from the superior longitudinal sinus directly into a glass syringe containing a few grains of potassium oxalate (approximately 0·5 per cent. of the weight of the blood drawn). By the use of the longitudinal sinus changes in the blood due to stasis, crying, and struggling were obviated. Admission of air to the syringe was avoided. Sufficient admixture of blood and oxalate was obtained during transference from syringe to centrifuge tube, and this did not expose the blood to loss of carbon dioxide or absorption of oxygen to any greater extent than occurs with the use of the M'Rae needle as described by Van Slyke.[3] Analyses were made at once. Duplicate determinations were carried out whenever there was sufficient plasma.

The alkali reserve is expressed as the volume per cent. of carbon dioxide which the plasma binds as bicarbonate at body temperature and the normal carbon dioxide tension of the alveolar air. Corrections are made for the temperature and barometric pressure at the time of analysis and the whole reduced to standard conditions of 0° C. and 760 mm. Hg pressure.

In the present paper the term "alkali reserve" will be used in relation to the numbers expressing the cubic centimetres of carbon dioxide bound as bicarbonate in 100 c.cm. of plasma. This seems permissible as an abbreviation, for the percentage of carbon dioxide is used as a measure of the available base. Since corrections are made for the free carbonic acid in the plasma, it seems also less confusing and more exact than the use of the phrase so frequently employed, "percentage of carbon dioxide." The sugar estimations were made according to the Lewis-Benedict [4] colorimetric technique. Routine urine analyses as made by the resident physician showed neither increased glycuresis nor ketosuria.

1. *Normal Infants.*

The blood was taken, as described, from healthy breast-fed infants gaining in weight, brought to the dispensary for circumcision. As a delay of one-half to one hour between the withdrawal of the blood and the separation of the plasma and corpuscles was unavoidable, the alkali reserve is probably slightly lower than it would have been had the determination been carried out at once.[‡] The number of hours after the last feed is obviously approximate. The value ranged from 43·3 to 63·3 (Table I.). This wide

---

[*] The term "acidosis" is used in the sense suggested by F. G. Hopkins at the recent meeting of the Section of Physiology and Pharmacology of the British Medical Association, as a diminution in the potential neutralising power of the blood.

[†] It is realised that a certain error occurs in the separation of plasma and corpuscles, and the subsequent subjection of the plasma to alveolar carbon dioxide tension, but the smallness of the error, and the greater facility of this technique for clinical purposes, determined its adoption.

[‡] Christiansen, Douglas, and Haldane [4] state that when serum and corpuscles remain in contact even for an hour there is a lowered alkali reserve of the plasma, due to ionic interchanges between cells and plasma.

the two cases of sudden respiratory failure described by Frey may have had a similar causation. Faber[9] has reported two cases with favourable results, and Levy[10] two successful results out of four cases treated, of which one relapsed.

The most recent communication is that of Jenny[11] who was able to stop fibrillation in 17 out of 18 cases. He states that in most instances the pulse has remained regular, but as the longest period of observation was only five months, obviously no statement as to the permanency of the cure could be made. He used from 0·5 g. to 15·5 g. in different cases, and says that it may be necessary to give the drug continuously or to repeat the courses; doses of 0·5 g. quinidine were given three times a day and found to be safe up to 2 g. to 3 g. The drug should be stopped at the least sign of disturbance in sight or hearing.

The purpose of this communication is to call attention to these observations, and to make a preliminary report of our results in the treatment of seven cases of auricular fibrillation.

CASE 1.—F. M., female, No. 43343/1921, aged 58, housewife. Mitral stenosis, auricular fibrillation. Three attacks of acute rheumatism in childhood. Then quite well until eight years ago; then a sudden attack associated with dyspnœa, palpitation, and partial loss of consciousness; since then has always suffered from shortness of breath and palpitation. A similar attack seven years ago. Subsequently admitted to an infirmary with swelling of legs and abdomen, and paracentesis abdominis was performed. Sudden attack two and a half years ago, with complete loss of consciousness, following which she came to the London Hospital as an out-patient. Since then auricular fibrillation has been constantly present, and courses of digitalis have been prescribed. Patient was admitted to the London Hospital August 2nd, 1921.

Condition on Admission.—Poorly nourished, rather wasted woman; no cyanosis, œdema, or dyspnœa; pulse absolutely irregular in volume and frequency, rate very variable at wrist, 62–112. Blood pressure: systolic 160, diastolic 96. Heart moderately enlarged to left; apex beat diffuse and wavy; systolic murmur at apex conducted outwards; pulmonary second sound accentuated. A polygraph tracing taken on August 4th, 1921, showed complete irregularity of both radial and jugular pulses, and absence of *a* waves.

Treatment and Progress.—On August 6th, quinidine gr. v. t.d.s. started. On the 11th, pulses perfectly regular, rate 50–60; no pulse deficit; a loud rumbling diastolic murmur not previously heard was present at the apex. Little change in the patient's objective condition, but she stated that the fluttering sensation in her chest constantly present for the last two and a half years had completely disappeared. On the 12th, quinidine discontinued; on the 13th, sudden onset of pain in left loin followed by four stools and hæmaturia. A little later pain in right upper abdomen; on examination tender palpable left kidney; diminished breath sounds and crepitations at right base; pulse still regular. On the 17th, condition improved; pain had gone, hæmaturia had ceased; occasional irregularity of pulse suggesting extra systoles. On the 18th, pulse completely irregular in volume and frequency; polygraph tracing showed complete irregularity of radial and jugular pulses with absence of *a* waves (see Fig. 1). On the 19th quinidine, gr. v. t.d.s., was started at 7.45 A.M.; at 9 P.M. patient suddenly complained of numbness and inability to move left leg. On examination, leg was cold; pulsation absent in dorsalis pedis but present in femoral artery; tendon reflexes were normally active; no disturbance of sensation; pulse completely irregular; diastolic murmur at apex had disappeared. On the 20th, leg warmer; good pulse in dorsalis pedis. On the 21st, tachycardia 130–140; pulse more regular. On the 22nd, tachycardia still present; polygraph tracings showed irregularity of radial and jugular pulses with absence of *a* waves. On the 23rd, pulse absolutely regular; tracings showed regular radial and jugular rhythms, and presence of *a* waves superimposed on *v* waves in the jugular pulse tracing. On the 24th, pulse-rate very variable, 76–112; polygraph tracings again taken; normal rhythm with presence of *a* waves. On the 29th, intermittent tachycardia continued. Tracings showed regular radial and jugular rhythms, *a* waves present and superimposed on *v* waves (see Fig. 2). Considerable improvement in patient's general condition. Complete absence of palpitation. A loud crescendo presystolic murmur was now heard at the mitral area. The pulse continued regular and on the 31st quinidine was reduced to gr. v. one dose a day. On the same night between 10 P.M. and 12 midnight the pulse became absolutely irregular. At 2 A.M. on Sept. 1st the pulse was regular and remained so until 10 A.M. on the 2nd, when it again became absolutely irregular. At the same time the presystolic murmur disappeared from the mitral area.

Summary.—A case of auricular fibrillation of about two years' duration. Reacted well to digitalis when under out-patient treatment and admitted fully compensated. Quinidine by the mouth was started and fibrillation ceased with return to normal rhythm on the fifth day after a total amount of gr. xcv. had been administered. The quinidine was discontinued and embolic infarction of left kidney and right lung occurred while the pulse remained regular. Six days after the quinidine was stopped fibrillation set in again; quinidine was at once re-administered and embolism of the left popliteal artery occurred before the heart returned to its normal rhythm. After four days of quinidine administration and when a total amount of gr. lx. had been given auricular fibrillation gave place for a second time to normal rhythm. Quinidine was then reduced and fibrillation recurred, but reverted to a normal rhythm in two hours, fibrillation again recurring eight hours later. Return to normal rhythm after fibrillation was proved by polygraph tracings and the appearance of a presystolic murmur.

CASE 2.—C. G., female, No. 43343/21, aged 32, housewife. Mitral stenosis, auricular fibrillation, myocardial failure. The patient was quite well until 21 months ago, when she had a "stroke" in the night, and on the following morning was found unconscious in bed with paralysis of the right side and later aphasia. She was admitted to Tottenham Hospital; ever since the attack patient had complained of shortness of breath, cough, and palpitation. Two weeks ago shortness of breath, cough, and palpitation became worse, with swelling of abdomen and legs. No history of rheumatic fever, chorea, or rheumatism.

On Admission.—August 4th, 1921, extreme dyspnœa, orthopnœa, and cyanosis; pulsation of congested veins of neck. Almost pulseless; pulse-rate almost uncountable at apex beat, but absolutely irregular in force and rhythm; apex beat 6¼″ from mid line; systolic murmur at apex beat conducted outwards. Accentuated pulmonary second sound; liver and spleen palpable; ascites and œdema of legs; old right hemiplegia. Immediate treatment: oxygen, intravenous strophanthin, venesection, and digitalis. Rapid improvement.

Treatment and Progress.—On the 8th, pulse 80; absolute irregularity in volume and frequency. Apex beat 4 inches from mid-line; no ascites; no œdema. On the same day, fully compensated when at rest in bed. Polygraph tracing shows complete irregularity of radial and jugular pulses with absence of *a* waves (see Fig. 3). On the 19th quinidine, gr. vii. t.d.s., started. On the 20th, after four doses of quinidine (i.e., gr. xxx.), pulse perfectly regular, rate 70–80; loud crescendo presystolic murmur now heard at apex beat. On the 22nd, pulse regular, polygraph tracing showed absolute regularity of radial and jugular pulses and the presence of *a* waves on the jugular pulse-tracings (see Fig. 4). On the 28th, pulse slow and regular; loud crescendo presystolic murmur at apex beat. Occasional extra-systoles not transmitted to radial pulse; polygraph tracing shows normal rhythm with no extra-systoles and presence of *a* waves; considerable improvement in general condition; complete relief from palpitation. Quinidine reduced to gr. vii. once a day. On Sept. 5th, pulse still regular; polygraph tracing showed presence of *a* waves.

Summary.—Admitted with failing compensation; reacted well to digitalis. Return to normal rhythm 36 hours after commencement of quinidine administration, and after a total dose of gr. xxx. had been given. Quinidine reduced to gr. vii.ss. once a day. Rhythm remained normal. Return to normal rhythm proved by polygraph tracings and the appearance of a presystolic murmur.

CASE 3.—R. N., male, No. 33074/21, aged 36, carman. Aortic and mitral incompetence, auricular fibrillation, myocardial failure. Acute rheumatism seven years ago; second attack six years ago; then well until two years ago, when he was admitted to London Hospital with complete iregularity of pulse, mitral systolic and aortic systolic and diastolic murmurs, enlargement of liver, ascites and œdema of legs. Since then always suffered from shortness of breath, palpitation, and swelling of legs.

On Admission.—August 18th, 1921, cyanosis, dyspnœa, and palpitation; no ascites or œdema of legs; apex beat 1 inch outside nipple-line; systolic murmur at mitral area; systolic and diastolic murmurs at aortic area. Pulse irregular in volume and frequency. Polygraph tracing showed complete absence of *a* waves and absolute irregularity of radial and jugular pulses (see Fig. 5). On the 20th, patient much better; pulse still irregular; compensated at rest in bed. Quinidine gr. vii.ss. started t.d.s. On the 24th, pulse still irregular; quinidine gr. x. t.d.s. At midnight 25th–26th, pulse regular; bradycardia; tracings taken showed normal rhythm of radial and jugular pulses with *a* waves present (see Fig. 6). G[illegible] improvement in patient's general condition[illegible] tation. Murmurs unchanged. Quinidine [illegible]

4. *Various Conditions.*

Table IV. contains a few analyses of the plasma of infants suffering from various disorders, not accompanied by hyperpnœa. All of them show normal reserves of alkali. Especially noteworthy are the cases of pylorospasm with vomiting on the day of the determinations and low percentages of sugar in the blood. Evidently sufficient sugar was being absorbed and burned to prevent an acidosis due to aceto-acetic acid. The cases of colitis, although severely ill with diarrhœa and fever, were not hyperpnœic and suffered no diminution in the plasma alkali.

Several cases of pneumonia are included here although they were inadequately investigated. In four (Cases 56, 58, 59 and 60) the reserves of alkali were below normal. The others had an apparently adequate supply of available base. Further study of the state of the blood in pneumonia is desirable. If the pulmonary epithelium does not permit the normal free diffusion of oxygen and carbon dioxide, it is possible that free carbonic acid increases in the blood, while oxyhæmoglobin decreases, leaving reduced hæmoglobin in excess. The hyperpnœa with cyanosis may be accounted for in this way. Such reactions as $Na_2HPO_4 + H_2CO_3 \rightleftharpoons NaHPO_4 + NaH_2CO_3$ with the excretion of the acid phosphate by the kidney, or the release of sodium from combination with hæmoglobin, may occur. *In any case, if the formation of* $NaHCO_3$ cannot keep pace with the accumulation of H_2CO_3 then the hydrogen-ion concentration is actually increased. Obviously this is possible with an amount of available base which is normal at the usual tension of carbon dioxide. *In this instance the tension of* carbon dioxide in the alveolar air cannot be taken as a measure of its tension in the blood, and the determination of the numerator of the fraction $\frac{H_2CO_3}{NaHCO_3}$ is *essential in estimating the true state as regards* acidosis. Although there may be a supply of available base adequate to deal with an increased production of stronger acids, the difficulty of excretion of the acids of lower ionisation would create a danger *analogous to a depletion of alkali reserve.*

The amount of available base appears to be uninfluenced by the height of the temperature.

Conclusions.

In certain of the diarrhœas of infancy, symptoms of intoxication, the chief of which is increased pulmonary ventilation, are accompanied by a reduction in the reserve of bicarbonate in the blood plasma. The hyperpnœa and the alkali reserve vary inversely. *The reserve can be increased to normal by the* administration of sodium bicarbonate. Hyperpnœa is thus controlled and the general toxic symptoms are alleviated, but the ultimate outcome, in the diarrhœal cases at any rate, is little influenced. It would seem that *either the pathological acid* possesses toxic properties even when neutralised (as is probably the case with aceto-acetic acid [7, 8]) and is not excreted as rapidly as it is formed, or the damage is so extensive before detection of the ensuing symptoms that *recovery is improbable.* Necropsy throws no light on the questions of the site or extent of the damage done. The usual lesions of gastroenteritis are the only ones found. Depletion of the alkali reserve is not a cause of the diseased condition, but is caused by it and is essentially, like an elevation of temperature or an acceleration of the heart rate, a varintion in a physiological constant, an indication of deranged function. And just as fever and tachycardia demand certain therapeutic measures for their own sake, so acidosis indicates the administration of alkali and fluid and the stimulation of excretion. When the acid produced and the cause of its production are known more specific therapy may be available. In conclusion, no more can be said than that these observations *confirm the work of* previous investigators.

Thanks are extended to Prof. Noël Paton, University of Glasgow, and to Dr. Leonard Findlay, Royal Hospital for Sick Children, Glasgow, for many valuable suggestions, for the selection of cases and opportunities for clinical observation. The investigation was done under the auspices of the Medical Research Council, by whom the expenses were defrayed.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF

PYONEPHROSIS AND URETERAL CALCULUS.

BY A. BERESFORD-JONES, M.B., B.S. DURH.,
SURGEON, KENT AND CANTERBURY HOSPITAL.

THE following case is of interest by reason of the large size of the calculus extracted from the ureter.

Mrs. D., aged 59, obese, gave a history of acute pain in right side of abdomen and right flank, of 11 days' duration. She stated that she had had previous attacks of pain during the past few years, and that her urine had contained blood. The physical signs were: tenderness, rigidity on right side of abdomen and in right flank; a mass was palpated in the right ileo-costal space, also a separate smaller tender mass in the right iliac fossa. The abdomen moved well on respiration. X ray examination showed a shadow over the right iliac fossa.

Operation (April 5th, '21). An oblique incision was made over the right ileo-costal space. The right kidney was found to be very much enlarged, the pelvis being distended. The whole mass was freed and the pedicle clamped; during this process the pelvis *ruptured, liberating* a large quantity of foul-smelling purulent fluid and urine. The right kidney was removed and the stump of the proximal end of the ureter followed down; a large lipoma was found surrounding a normal-sized ureter at about the level of the crest of the ilium. Lower a stone was discovered in a dilated ureter. The lipoma, ureter, and stone were removed, the ureter stump ligated, and the wound drained and closed in layers. The patient made an uninterrupted recovery, and was discharged from hospital on May 13th. On Oct. 19th patient reported, being then quite well. Examination of abdomen revealed nothing abnormal. Scar healed. No bulging or hernia. Urine normal.

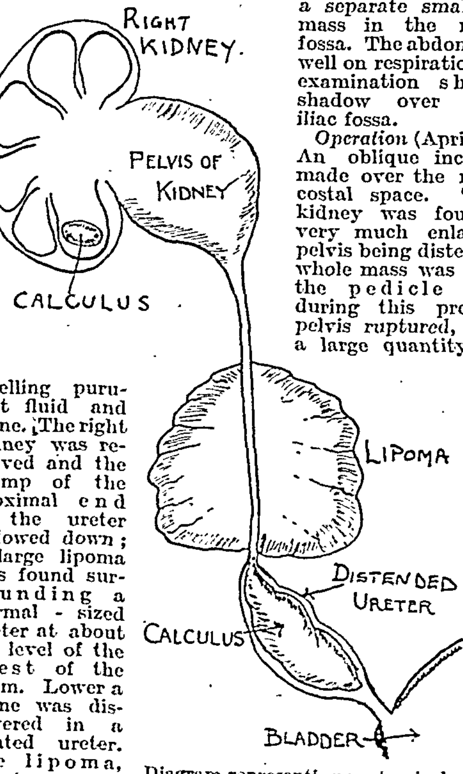

Diagram representing anatomical sequence of structures encountered during operation.

a day. On the 27th, sudden onset of pain in left side; no physical signs in lungs; spleen not palpable, but tenderness on palpation under left costal margin; probably splenic infarction. On the 29th patient felt very well; pain completely gone; no palpitation. Polygraph tracings showed complete normal rhythm.

Summary.—Auricular fibrillation of two years' duration, admitted with failing compensation; reacted well to digitalis; return to normal rhythm five days after commencement of quinidine administration and after a total amount of 157 gr. Embolic infarction of spleen 24 hours after return to normal rhythm; quinidine reduced to gr. x. once a day; remained regular.

CASE 4.—F. O., No. 4335/21, aged 45, housewife. Auricular fibrillation, mitral incompetence, myocardial failure. Had chorea 35 years ago; three attacks of acute rheumatism 24–19 years ago, since when she has always suffered from shortness of breath, palpitation, and præcordial pain. Admitted to the London Hospital 15 months ago, eight and a half months pregnant, with auricular fibrillation, severe dyspnœa, ascites, and œdema of legs. Reacted well to digitalis and passed successfully through a normal labour, giving birth to a live child; since then has been attending as an out-patient; auricular fibrillation constantly present.

On Admission.—August 2nd, 1921, poorly nourished woman; congested facies, dyspnœa, orthopnœa, and cyanosis. Pulse absolutely irregular in volume and frequency; heart moderately enlarged to left; mitral systolic murmur and accentuated pulmonary second sound. Congestion and œdema of lungs; palpable liver; ascites and œdema of legs.

Treatment and Progress.—Immediate treatment, digitalis, to which the patient responded well; this was stopped after nine days on account of nausea. On the 18th the patient was much better; œdema and ascites were absent; pulse-rate was much less and pulse deficit reduced. Polygraph tracings revealed absolute irregularity of radial and jugular pulses with absence of *a* waves (see Fig. 7). On the 19th quinidine, gr. v. t.d.s., was started; on the 24th digitalis was re-started on account of tachycardia; on the 31st quinidine was increased to gr. x. t.d.s. Frequent polygraph tracings revealed the persistence of fibrillation and the absence of normal rhythm, and this condition continued up to Sept. 2nd, when, however, the patient's general condition was much improved, and a completely irregular rhythm seemed to have given place to one in which phases of comparative regularity alternated with phases of tachycardia, but polygraph tracings failed to reveal presence of *a* waves. On the 3rd digitalis was stopped. On the 5th at 6 A.M. the pulse was absolutely regular and continued so all day. Polygraph tracings showed a completely regular cardiac rhythm with presence of *a* waves (see Fig. 8).

Summary.—A case of auricular fibrillation of about 15 months' standing which reacted well to digitalis. Normal rhythm was restored after quinidine had been administered for 18 days and a total quantity of 315 gr. had been given.

CASE 5.—S. E., No. 43563/21, aged 35, housewife. Myocardial failure, auricular fibrillation, mitral stenosis, and incompetence. Shortness of breath on exertion dating from an attack of influenza three years ago. A year and a half ago an attack of bronchitis. On first getting up after three weeks in bed, sudden loss of consciousness, followed by exhaustion, breathlessness, palpitation, and pain in the chest, which have persisted ever since. Hæmoptysis, followed by œdema of legs, nine weeks ago. No history of chorea, rheumatism, or rheumatic fever.

On Admission.—August 20th, 1921, poorly nourished, sallow woman; heart enlarged outwards and downwards; dyspnœa; systolic and diastolic murmurs at mitral area; absolute irregularity of pulse; tachycardia; a few crepitations at both bases; palpable liver; no ascites or œdema of legs.

Treatment and Progress.—Tinct. digitalis ℥xxx., four doses. After three days much better; no dyspnœa while at rest in bed. On the 22nd polygraph tracings revealed complete irregularity of radial and jugular pulses with absence of *a* waves. Quinidine, gr. vii.ss, t.d.s., was then started; but on the 27th it had to be suspended on account of diarrhœa and abdominal pain. On the 28th there was no diarrhœa or pain; quinidine was re-started. On Sept. 1st patient developed a scarlatiniform rash. On the 5th pulse was still irregular. Repeated polygraph tracings showed the continuation of auricular fibrillation up to this date.

Summary.—A case of auricular fibrillation of unknown duration which failed to be arrested by 300 gr. quinidine administered over a period of 15 days. Ill-effects observed attributable to the drug were abdominal pain, diarrhœa, and a scarlatiniform eruption.

CASE 6.—J. L., No. 33010/21, aged 37, carman. Auricular fibrillation, myocardial failure. Six months ago short of breath; five months ago his right foot suddenly went numb, cold, and white. Admitted to the London Hospital with auricular fibrillation, palpable liver, mitral systolic murmur and œdema of lungs; reacted well to digitalis and was discharged. Return of exhaustion and shortness of breath one month ago.

On Admission.—August 2nd, 1921. Well-nourished man; dyspnœa, orthopnœa, and cyanosis. Pulse absolutely irregular in volume and frequency; heart enlarged to left; mitral systolic murmur and accentuated pulmonary second sound; crepitations at both bases. Palpable liver; no ascites or œdema.

Treatment and Progress.—Reacted well to digitalis, which was stopped on August 18th. On August 23rd, 1921, polygraph tracings were taken which revealed absolute irregularity of radial and jugular pulses with absence of *a* waves (see Fig. 9). Quinidine, gr. vii.ss. t.d.s., was then started. On the 27th, quinidine was increased to gr. vii.ss. six-hourly. On Sept. 1st quinidine was increased to gr. x. six-hourly. At 4 A.M. on the 5th one dose of tinct. digitalis, ℥ xxx., was given. The pulse remained completely irregular until 6 A.M. on the same day, when irregularity gave place to a normal rhythm. Polygraph tracings (see Fig. 10) demonstrated complete regularity of radial and jugular pulses with presence of *a* waves.

Summary.—A case of auricular fibrillation of about 15 months' duration which reacted well to digitalis. Normal rhythm was restored after quinidine had been administered for 18 days, when a total quantity of gr. 375 had been given. Ill-effects observed attributable to the drug were abdominal pain, diarrhœa, and profuse sweating.

CASE 7.—R. P., No. 3564/21, aged 42, housewife. Auricular fibrillation, mitral incompetence. Rheumatic fever ten years ago. Since then quite well until 18 months ago, when she started to have shortness of breath, pain in the chest, and palpitation. One year ago admitted to the London Hospital with auricular fibrillation, dyspnœa, and œdema. Did not react well to digitalis, but improved with prolonged rest in bed. Since then shortness of breath on exertion, palpitation, and præcordial pain.

On Admission.—August 20th, 1921, very obese Jewess. Short of breath; absolute irregularity of pulse; heart enlarged to left; mitral systolic murmur and accentuated pulmonary second sound. No œdema. Fairly well compensated.

Treatment and Progress.—On the 22nd tracings showed absolute irregularity of radial and jugular pulses with absence of *a* waves. The same day quinidine, gr. vii.ss. t.d.s., was started. On the 24th tinc. digitalis, ℥ xxx., four-hourly, was started and continued for six doses. On Sept. 1st patient developed a scarlatiniform rash. On the 2nd, quinidine was still being administered. Polygraph tracings revealed the persistence of auricular fibrillation, and there was no alteration in the nature of the cardiac rhythm.

Summary.—A case of auricular fibrillation of about one year's standing which reacted poorly to digitalis. Quinidine (262 gr. administered over a period of 12 days) failed to produce a return to normal rhythm. Ill-effects observed, attributable to drug, were abdominal pain, pain in the back, sweating, and scarlatiniform rash.

Discussion of Results.

From the foregoing case reports it will be seen that out of 7 cases of well-established auricular fibrillation in 5 the administration of quinidine by the mouth has been associated with return to the normal cardiac rhythm. In all these five cases the change has been demonstrated by polygraph tracings, and in two of them by the appearance of a crescendo presystolic murmur at the apex. In one of these five relapse occurred soon after the drug was stopped, and again a second time when the dosage was reduced. In two the dosage was only decreased and there was no relapse into auricular fibrillation. In two of the five cases, shortly after the onset of normal cardiac rhythm, embolic infarction of internal organs occurred. The formation of clots in the appendix of a fibrillating auricle is not uncommon, and the loosening of these by restored auricular contraction and their projection into the general circulation is easily understood. The only reference we have been able to find in the literature to a similar occurrence is in a paper by Benjamin and v. Kapff, who report one instance of lung embolism and one of sudden death possibly due to the same cause. In one, tachycardia was associated with the administration of the drug. In one case an alteration of cardiac rhythm, characterised by an alternation of phases of comparative regularity with bouts of irregular tachycardia, preceded return to normal rhythm.

The pharmacological action of quinidine is still undetermined. Electro-cardiographic study has shown

Remarks.—Jan. 28th: Decided improvement. Feb. 1st: Still improving.

A further six treatments of an exactly similar nature were given on Feb. 8th, 15th, 22nd, March 1st, 7th, 15th, when the patient was discharged with normal hearing.

CASE 3.—Mrs. D., aged 35. Chronic otitis media, left ear. Had scarlet fever at 6 years, leaving a discharge from the left ear which eventually disappeared only to return, accompanied by severe pain, each time the patient has a cold. She had an abscess behind the left ear when 21 years of age and had all her teeth out. She is quite deaf on the left side and has a damaged membrana tympani. The tympanum is adherent in parts. Tr. began Jan. 19th, ended Feb. 28th, 1921.

" 8th	5	2	1½
" 28th	6	2	1½

Remarks.—Feb. 28th: Returned for examination; later discharged; otitis cured and hearing excellent.

It is rather surprising to find, on adding up the sum total of the actual time occupied by the treatments, that even in a case extending over so long a period as the first treatment occupies little more than an hour in all, and in such a case as the last just over 20 minutes.

It is quite impossible to lay down hard-and-fast lines as to methods of treatment, length of exposure, &c., which can only be acquired by experience of cases differing widely according to constitutional and disease conditions.

NEWCASTLE-ON-TYNE POST-GRADUATE COURSE.—The course of lectures and demonstrations for the Michaelmas term began on Oct. 13th. The classes which have been arranged are as follows: Clinical Medicine, Dr. W. E. Hume and Dr. A. Parkin; Diseases of the Throat, Nose and Ear, Mr. S. S. Whillis and Mr. W. F. Wilson; Clinical Pathology, Prof. Stuart McDonald and Dr. A. F. Bernard Shaw; X Ray and Electrical Treatment, Dr. W. D. Arnison; Midwifery and Gynæcology, Prof. R. P. Ranken Lyle; Neurology, Dr. Geo. Hall. Thirty-six practitioners have entered for the various classes, which will meet in the Royal Victoria Infirmary every Thursday up to and including Dec. 15th.

Medical Societies.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

A MEETING of this Association was held on Oct. 21st, with Mr. R. C. ELMSLIE in the chair, when Dr. A. E. SANDERSON CLOW opened a discussion on

GAMES FOR GIRLS.

She said that she would confine her remarks entirely to her own experiences when a girl, and to her observations on the school girls and patients with whom she had come into personal contact. She thought the time long past when there would be any occasion to deal with arguments attempting to prove that field games like cricket and hockey were bad for girls. However, from letters that had appeared in the press during the last few months, it seemed that the matter was still in dispute even among educational authorities. Probably everyone nowadays was agreed that girls must have *some* outdoor recreation, though a girl was often expected to bear the strain of school life and develop her maximum physical strength on a much smaller ration of fresh air and exercise than was deemed necessary for her brother. The varieties of outdoor recreation within the reach of school girls were: walking, cycling, swimming, drilling, and gymnastics; and games—including cricket, tennis, and rounders in the summer; hockey, lacrosse, and net-ball in the winter. As to walking and cycling, the latter was good enough exercise for the legs and thighs, but gave no exercise to the abdominal muscles, nor to the arms and shoulders. Walking was doubtless a very good exercise, but should not be the only one taken throughout the week because the muscles of the back, abdomen, shoulders, arms, and neck were only very partially brought into play. Also it did not afford the same mental diversion or lessons in esprit de corps. Dr. Clow praised swimming as one of the most popular and exhilarating of sports. Drilling and gymnastics, she thought, were excellent in moderation, especially if conducted in the open air, but they did not take the place of games. Drilling was valuable not only as a corrective to stooping and bad habits in standing; it taught concentration and quickness in understanding and obeying orders, and discouraged the desire to show off. Dr. Clow had never seen any ill-effects on girls from gymnastics, and saw no reason why they should not be as beneficial to girls as to boys, while elaborate apparatus was not needed. With regard to outdoor games, the best games for school girls were team games—for example, cricket, hockey, and lacrosse. Criticisms of these games came mostly, she said, from elderly men, or from women who had not had the advantage of playing these games themselves. The important part played by games in the character building of boys had been recognised for generations; girls stood in need of these lessons just as much as did boys, and had the same need of games as an aid to health. Games could be considered in the light of their effect on character, their effect on the mind, and their effect on the physical health during school and adult life. As to the first point there was, in Dr. Clow's opinion, no part of the school curriculum which had more effect on the formation of character than had field games. Besides learning lessons of discipline, endurance, and fair play, the girls learned as children that a certain part of the day should be set apart for outdoor exercise, and, on the other hand, that however engrossing a game might be, the time allotted to it should be subject to definite limits. They learned, moreover, lessons of hygiene and of good citizenship. Dr. Clow, in speaking of matches, remarked that children should not be allowed to play in a match without having the opportunity of micturition immediately beforehand. Many children suffered from rapid urinary excretion under excitement, and the harm that a girl might suffer in playing a vigorous game variation in infancy, with a tendency to be low, has been noted before, although not explained, except perhaps by the suggestion of Marriott that the more active metabolism of infants, with its greater production of acids, may lead to a decrease in alkali reserve.

2. *Cases of Dyspepsia.*

In this group were cases with gastro-intestinal *disorders of an afebrile, non-toxic variety, with more* or less diarrhœa and occasional vomiting (Table II.). The alkali reserve ranged between 45·5 and 70. Cases 13 and 14 are of interest. They both received alkaline therapy before the analyses were made, and in both there was a reserve of alkali greater than is usually found in infants. This reserve gradually decreased, and the last analyses made showed a diminution below the level of safety, although there were then no symptoms of intoxication. Subsequently intoxication developed and both patients died. Three patients (Cases 12, 19 and 26) showed neither diminution in alkali reserve nor symptoms of intoxication, but died of marasmus.

There does not seem to be any relationship between the age or weight of the child, the caloric intake or the blood sugar, and the alkali reserve.

3. *Cases with Intoxication.*

There were 14 cases showing the clinical symptoms of intoxication with the typical increased pulmonary ventilation or hyperpnœa without cyanosis (Table III). Of these, one (Case 10) had a carbon dioxide combining power of 30·9 and recovered without any specific therapy. Whether this was an acidosis due to starvation or to administration of drugs before admission is not known. Improvement occurred within a few hours. Case 49, admitted with convulsions, had been starved for three days. He then developed typical symptoms of acidosis with air hunger and abundant diacetic acid and acetone in the urine. The alkali reserve of the plasma was 38. With bicarbonate of soda, 1·3 g. four-hourly, an intraperitoneal hypertonic saline injection, and an adequate caloric intake, all symptoms disappeared and the alkali of the plasma returned to normal. This was in all probability a case of acidosis due to ketones—that is, the beta-oxybutyric and aceto-acetic acids depleted the alkali reserve. Were these, however, caused by the starvation alone? Veeder and Johnstone[6] find that the "acetone bodies" produced in children by 48 hours of starvation cause no symptoms and are not dependent on the previous condition of the child. However, no cases with severe convulsions were included in their investigation. Some other acid related to the original morbid condition may have increased the acidosis in this case. All the other patients died. One case (39) was considered to be an example of diarrhœa with intoxication, but he had slight cyanosis and a positive von Pirquet reaction with a normal alkali reserve. Doubtless, this case should not be included in this group, but owing to the first clinical impression it has not been omitted. All those cases which received alkaline therapy maintained a normal alkaline reserve so far as it was observed. Estimations were not made immediately before death. The fatal outcome, however, was not averted. Also, in the two cases (13 and 14, Table II.) which received bicarbonate of soda before the appearance of toxic symptoms, intoxication and death were not avoided. The alkali was always given by mouth in doses sufficient to keep the urine alkaline. More vigorous intravenous administration was never tried.

Dr. Clow and Miss Stansfeld were very welcome. He trusted that in the future no attention would be paid to remarks made without facts to support them. On the question of cycling for small children he suggested that more attention should be paid to fitting the cycle to the size of the child, so that the child should use the calf muscles instead of shifting the weight from side to side. He regarded mixed hockey as unsatisfactory, as women were apt to be overstrained in order to keep up with men. The weapon or ball should always be proportionate to the size of the child.

Miss P. Laurence (Roedean School) agreed with all the views expressed by the openers of the discussion except with regard to games during menstruation. At Roedean the girls did not play games during the first three days. Her experience extended over 36 years and 3000 girls had passed through Roedean, of whom many had married and sent their girls back to be educated. The medical officer who had been attached to the school for many years having resigned, Dr. Louisa Martindale, the new medical officer, had sent in a report as a result of her medical examination. She found that those girls who had been four years in the school were in very good physical condition and compared favourably with new girls. This she attributed to physical training in the open air. Miss Laurence praised games for their mental, moral, and pleasurable effect. If games were abolished the tone of the school would be ruined. It was possible to overdo anything, for example to over-eat, but games in moderation did the normal girl nothing but good.

Dr. M. Dobbie suggested that schools where games were played for much shorter times were in a different category from training colleges as regards continuous exercise during menstruation.

Dr. L. Fairfield said that not only in the lay press but in many gynæcological text-books were to be found remarks derived from intuition rather than fact on this subject. The lack of coördination during menstruation experienced by students was interesting, inasmuch as the superintendent of a resident institution for the blind informed her that the girls' aptitude for learning Braille was markedly affected during menstruation. She had had difficulty in getting any accounts of dysmenorrhœa from large training colleges under her medical supervision. She asked for opinions on sport such as football and boxing for girls. She disapproved of the former because of the strain on the pelvic region and of both because there was risk of injury by direct force, for example, on the breast. She asked for the expression of a medical opinion on this subject because the motives of those encouraging girls to play football were not always unexceptionable. From her experience of girls in the Air Force Dr. Fairfield concluded also that motor-cycling sometimes increased dysmenorrhœa—possibly because of the vibration and the effort of starting—and had tried to secure rest for the girls during the first day of menstruation. As to games after meals, games on an empty stomach were unsatisfactory. Some children were never able to enjoy their sport because it was timed after a long spell of work when they were tired and hungry. She was glad to hear Dr. Clow's remarks on bathing during menstruation; she hoped that the ridiculous superstition against baths during menstruation would be abolished. Dr. Fairfield spoke from experience of 22,000 girls in the Air Force. Clerks and domestic workers were those who suffered most from dysmenorrhœa. Varicose veins was notoriously a disease of the classes who did not play games much.

Mrs. M. Scharlieb pointed out that figures might be difficult to collect in England but that nature had provided results of a gigantic experiment in India. The well-born Brahmin girl suffered from want of development of her moral nature and of her abdominal muscles, and suffered proportionately when in labour. On the other hand, among the low caste road-makers, the women did hard work in the open air, and were able to return to work immediately after bearing a child.

Miss C. Cowdroy (Crouch End High School) voiced her objections to games for girls on the lines of her letter published in The Lancet of May 14th, 1921.

Miss N. Nicholls (Lady Holles School) suggested that the same number of The Lancet which contained Miss Cowdroy's letter happened to contain an account of Prof. Arthur Robinson's views that a certain amount of pre-natal death is normal and not due to disease of either parent. These figures were based on mares and ferrets and showed at least how cautious we should be in attributing sterility to any definite cause such as games. In the same issue of The Lancet was a report of a discussion on Sterility at the Royal Society of Medicine, where it was suggested that statistics to be of any value should be based on not less than 1000 marriages, each of which had lasted not less than 15 years, the wife being under 35 and the husband under 40 at the time of marriage. As the Education Act had only existed since 1902 it was evident that many schools had not existed long enough to collect statistics of any value, but that the medical officers of this Association would be in the position to supply valuable information in the future if they kept records. Miss Nicholls expressed anxiety lest criticism directed against games should be thought to be based on ascertained facts, because games cost money for ground and apparatus. If the present wave of economy should take the form of depriving of games those who could not afford them without help, in her opinion economy on games would mean economy on health.

Dr. Stansfeld, in reply to a question whether those who go to physical training colleges were not of exceptionally good physique, pointed out that her argument was not that these girls were typical but that they suggested that an athletic life had at least no detrimental effect. In answer to another question about sculling she said that no bad effects had been noticed from this exercise. Racing was always an exceptionally strenuous form of sport.

The President said that it was bad for anyone to enter into competitive games unless properly trained. It was essential that exercise should be kept within limits and standardised in accordance with the age and strength of the child.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

Exhibition of Cases and Specimens.

The session's meetings of this Section opened on Oct. 14th, with Dr. James Taylor, the President, in the chair.

Miss Ida C. Mann showed a series of models illustrating the development of the human eye.

Probable Implantation Cyst.

Mr. L. Fleming showed a case of probable implantation cyst in a girl who received an injury to the eye 18 months ago. When seen six months after she had a perforating lesion at the limbus with adherent iris, and active iritis was present. Six months later a small nodule appeared in the "nine o'clock" position, but it had not since appreciably increased in size.—Mr. Treacher Collins was doubtful as to its nature, but suggested contact illumination to help in its diagnosis.

Grey Mass in Vitreous.

Mr. J. S. Bookless showed a child with a grey mass in the vitreous, with arborising vessels visible at the back of the lens. A week after being seen a small nodule appeared on the back of the iris. This had progressively increased, and vision was reduced from 6/36 to perception of fingers at a distance of a few inches. The diagnosis seemed to rest between a congenital abnormality and malignant disease.—Sir William Lister regarded it as a cyst of the iris, with a membrane which had formed after the occurrence of hæmorrhage in the vitreous. He did not think it was malignant.—Mr. M. S. Mayou referred to a case of similar appearance which he had shown, but without the membrane. He agreed that it was a cyst of the iris.

Specimen.—Kidney enlarged, cortex thin, calices dilated; small stone at lower pole of kidney; pelvis of kidney enlarged, tapering off into normal-sized ureter surrounded by lipoma the size of a closed fist; immediately below this lipoma a large calculus[1] 8·4 cm. in length, 8·8 cm. at widest circumference, and weighing 48·5 g.

The writer would be glad to hear of any explanation of the presence of the lipoma in the above-mentioned position.

BELLADONNA POISONING FROM EATING RABBIT.

BY DOUGLAS FIRTH, M.D. CAMB., F.R.C.P. LOND.,
JUNIOR PHYSICIAN, KING'S COLLEGE HOSPITAL;
AND
J. R. BENTLEY, M.D. CAMB.

THERE appears to be some uncertainty of opinion as to whether belladonna poisoning can follow eating the flesh of a rabbit which has been feeding on *Atropa belladonna*; the majority of text-books on toxicology make no reference to the possibility. "Blyth" says[2]: "It is the general opinion that rabbits may eat sufficient of the belladonna plant to render the flesh poisonous and yet the animals themselves may show no disturbance in health. But this must not be considered adequately established." Another authority, Glaister,[3] states that "rabbits may be fed exclusively on the leaves [of *Atropa belladonna*] for days without inconvenience, though it produces a dilatation of their pupils as in man," but no reference is made to poisoning in man by this agency. The incident here related seems to prove that the general opinion referred to by Blyth is correct.

A greengrocer, while buying vegetables for his shop, was given a rabbit which had been snared that morning in a district where *Atropa belladonna* is known to grow. Having previously been a fishmonger and poultry-dealer, he prepared the rabbit himself for consumption, noting that it appeared to be in every way in excellent condition. The rabbit was stewed by his wife, and at 1 P.M. these two and their assistant, a girl aged 20, partook of the dish. After the meal, the girl, while washing up the plates, noticed her mouth was dry and procured a drink of water, being shortly joined by the elder woman in the same plight. Soon afterwards they were greatly alarmed by "failing vision," and on calling to the man for assistance, found him in a similar condition. One of us (J. R. B.) was then summoned and saw the patients about 3 P.M.; all presented the typical picture of mild belladonna poisoning—pupils dilated, dry mouth, giddiness, and rapid pulse. After the usual procedure in cases of poisoning, inquiries were made for the source of the poison, but the only thing taken in common was the rabbit for dinner. At 9.30 the same evening we saw the cases together. The man and his wife were better, though the pupils were still widely dilated, and a marked scarlatiniform rash had appeared on the girl. We elicited the information that a dog and a cat in the house had been given some of the rabbit, and an examination of the pupils of both showed them to be dilated and immobile to light. A portion of the rabbit, including the liver, was taken and submitted to analysis. The report on the analysis states that chemical examination of the portion of cooked rabbit showed that a small quantity of alkaloid was present, giving a definite reaction by the Vitali method for belladonna alkaloids.

Remarks.

The rabbit was fresh and, to an expert eye, in good condition. No green vegetables had been cooked with it. Symptoms of belladonna poisoning followed the eating of the flesh in three human beings and two animals, and belladonna alkaloids were found in the flesh. In spite of the enormous number of rabbits consumed yearly, belladonna poisoning through their agency is far from common; this may be due to the universal prejudice against eating rabbits in the spring, summer, and early autumn, the time when the belladonna plant flourishes and affords the rabbit an article of diet.

What amount of atropine was ingested by our patients it is impossible to say. Blyth[4] gives ⅛ gr. as the dose which may be expected to give rise to toxic symptoms, and seeing that barely half the rabbit was eaten, the whole body must have contained at least 1 gr. of alkaloids, affording a hearty eater the opportunity of taking a fatal dose.

A NOTE ON THE TUNGSTEN RAYS.

BY W. J. BURROUGHS, M.R.C.S. ENG.

THE tungsten rays as a method of treatment is comparatively recent, and any additional facts as to their utility as a curative factor in medicine may therefore be of interest. The tungsten arc produces, besides light and heat rays, ultra-violet rays; these ultra-violet rays are beyond the limit of the visible spectrum, which ends at Δ = 3800, and it has been found by experiment that when directly applied are strongly bactericidal between Δ = 3100 and Δ = 2230. I have been working for the past six months with an apparatus consisting of two electrodes of pure tungsten actuated by a current of 100 volts and 5 amperes and the results have, on the whole, been most promising.

In all cases of superficial suppuration in which I have tried it, a complete cure has resulted in about 8 to 12 treatments. Among these cases were the following. A poisoned and suppurating index finger of two months' duration, entirely healed with 6 applications; an old varicose ulcer, healed in 8 applications; a case of suppurating cervical glands of six months' standing, with a large swollen inflammatory area extending from the horizontal ramus of the jaw to the clavicle, entirely cleared up with 14 applications; and a case of impetigo contagiosa on face and scalp of a child, aged 2, cleared up in 6 applications. The same curative effects may be noticed in pustular discharges from the ear. Indeed, the tungsten ray has not only proved of great value in suppurative conditions but also in cases of middle-ear deafness generally.

Ear Treatment.—The ear treatment, which is applied by means of a specially made parabolic quartz-fluorite reflector, absorbing a portion of the ray, is of short duration, the earlier treatments lasting only 2¼ minutes for each ear, if both are affected. That is to say, 1¼ minutes' application is given through a suitable speculum to the tympanum, and 1 minute's application over the mastoid cells. The beam is made to focus on to the surface under treatment at a distance of 18 in. from the reflector. The patient's eyes must be protected with a shade of some kind and the operator uses special leaded blue glasses. In cases of otosclerosis a treatment as described above may be given every two or three days, the length of the exposure being increased to 2½ minutes for the internal application and 1½ minutes for the external. The improvement in the hearing is, as a rule, noticeable after the fifth treatment, but may appear earlier. In cases complicated by Eustachian catarrh or catarrh of the respiratory passages the fumes given off by the ray, inhaled through a suitable inhaler, are found to have a beneficial effect. A course of about 8 to 12 treatments is given, and the patient is asked to return in a fortnight in case any further treatment is required.

Typical Cases.

In recording the treatments of three typical cases, Tr. = treatment. Ty. mins. = time of application to tympanum in minutes. Mc. mins. = time of application to mastoid cells in minutes. Inh. mins. = time of exposure to inhalation in minutes.

CASE 1.—Mrs. A., aged 55. Chronic otitis media of the right ear of old standing; patient unable to give exact duration. Deafness in affected ear very pronounced. First tr. given on Dec. 1st, 1920, last tr. on April 5th, 1921.

---

[1] Other large ureteral calculi have been reported in the following numbers of THE LANCET: 1913, ii., 1456; 1920, i., 150, 767.—ED. L.

[4] Blyth: Loc. cit., p. 393.

held that the man should have a reasonable period within which to make an effort to do some work. At the end of such period benefit might be suspended if no genuine effort had been made.

"Incapable of Work": Its Meaning.

The question whether the words "incapable of work" should be read as meaning "incapable of remunerative work" has never been expressly decided although it has been raised. In the opinion of Mr. Ball, it was not possible to cite cases decided under the Workmen's Compensation Act as parallels, since the provisions of the Workmen's Compensation Act are expressly designed to compensate for loss of earning capacity. In one case an appellant who had been ruptured in the course of his employment made a successful claim against his employers and was awarded 7s. a week on the ground that, while not wholly capacitated, he was only capable of doing light work. His claim upon the funds of his society, however, failed, because the county court judge had, in effect, decided that he was capable of work.

A difficult question arises when an insured person has been rendered incapable, and undergoes a course of training to fit himself for other work. Is he entitled to sickness benefit during the period of training? It would seem from the following case that he is not. A draper's assistant who had lost an eye in the army worked as a milk porter for six months after his discharge, and then had to return to hospital on account of his injury. He was discharged from hospital with a reduced pension. During the next five months he worked for three separate firms of linen-drapers, but was discharged from each owing to the state of his health. In April, 1920, his doctor certified that he was unable to follow his previous occupation; his full pension was restored, and he was sent for training as a bricklayer. His claim for sickness benefit, however, was refused on the ground that he was still capable of doing light work. The court's expression of opinion with regard to "training" was important: "There may be cases in which a man undertaking a course of training is not capable of any form of work, and is accordingly entitled to sickness benefit until his training is partially or wholly completed . . . but where the appellant is capable of light work, however prudent a training may be. . . . the Act does not allow sickness benefit to be paid." If an insured person is compelled to make use of a surgical instrument in order to be capable of work, he becomes eligible for sickness benefit, should he, by accident, be deprived of his instrument. This was decided in a remarkable case in which the appellant had lost both his legs in an accident, but was able to work with artificial limbs. Having broken one of these legs he claimed sickness benefit from his society. The society refused to pay on the ground that the incapacity ceased when it was established that he could work continuously with artificial legs, but the court upheld the man's claim.

Duties and Powers of the Insurance Doctor.

Referring to the duties and powers of the insurance doctor Mr. Ball said that the proper working of the Act depended very much on the judicious signing of certificates. The doctor's certificate was not final, but was most important. The certificate should be reasonably explicit, and, if necessary, the doctor should insert qualifying words on the printed form before signing it. Mr. Ball said he believed it was on record that a doctor had given a certificate to the effect that a man was "still incapable of work." It was true enough, but he might have amplified it a little. He might have said, "still is, and in all probability will remain, incapable of work." The man was dead. When a case is referred to a medical referee, it is advisable that the insurance doctor who has signed a certificate should see his patient gain if he is going to appear as a witness to contradict e referee. In a recent case, a woman had received kness and disablement benefit continuously from January, 1918, to February, 1920, upon the certificates of her panel doctor that she was suffering from bronchitis. After examination by the referee, whose opinion that she was fit for work, was confirmed by an umpire, payment was stopped. Her panel doctor, who appeared as a witness on her behalf, admitted not having examined her about the time of the medical referee's examination. In these circumstances the court disallowed her claim. It was advisable that the panel doctor and referee should collaborate, and, if possible, the former should be present at the time of the latter's examination and lay all relevant facts before him.

Discussion and Reply.

Dr. **HENSLOWE WELLINGTON** said he had acted as medical referee to an Approved Society since 1914, and had inquired into nearly 7000 cases in four years. His experience convinced him that there was very little true malingering, but there was a tendency on the part of some of the insured persons to prolong their convalescence unduly.

Dr. **M. I. FINUCANE** believed that insurance medical officers had been somewhat careless in signing certificates and had thus lost the confidence of the Approved Societies, who otherwise might now have been more ready to support the panel doctor in his effort to retain the present capitation fee.

Surg.-Captain **M. H. KNAPP**, R.N., asked whether a man "in quarantine" on account of an infectious fever was entitled to sickness benefit.

Dr. **J. HALLIDAY SUTHERLAND** agreed that there had been very little malingering before and during the war when wages were high, but considered that it was now increasing. There should be heavy penalties for incorrect certification of unfitness.

The **PRESIDENT** said that there had been some condemnation of the panel doctor, but very little appreciation of much of his good work. He thought it was quite natural for the doctor to give his patient the benefit of any doubt that might exist when signing certificates. He was surprised there were so few appeals against decisions of Approved Societies, since the cost to the applicant of an appeal was only a guinea. In his opinion "incapacity for work" meant "incapacity to earn wages," and the interpretation of the Workmen's Compensation Act would be useful as a standard in settling questions under the National Health Insurance Act.

Mr. **VALENTINE BALL**, in reply, said that his paper had emphasised the importance of correct certification, as certificates affected also unemployment pay, which could only be drawn by a man who was "capable of work." In reply to Surg.-Captain Knapp he said that the onus of deciding whether a man "in quaratine" was capable of work would fall on the doctor. His paper had borne fruit already in the expression of opinion on the interpretation of the Act it had won from the learned President.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

AT the first meeting of the session of this society, held at 11, Chandos-street, London, W., on Oct. 20th, Sir **JAMES CANTLIE**, the President, occupied the chair and delivered an inaugural address on

Life Insurance in the Tropics.

He drew attention to the frequency with which insurance premiums were allowed to lapse by young men in the early stages of their careers in the tropics, owing to financial stress and the extra premium usually charged to cover the supposed additional risk of living in a tropical climate. He estimated that in two out of every three cases the payment of premiums was dropped, necessarily to the great advantage of the insurance companies, which might therefore be encouraged to maintain the extra charge. The first five years of a young man's life in the tropics afforded the most critical period, and in some measure justified the higher premium, with an overdistended bladder was obvious. On many playing fields there was still no lavatory accommodation provided, and this matter should be remedied.

Effects on the Reproductive Organs.

The beneficial effect on the physical health of running and bending and stretching exercise in the open air was generally acknowledged, the only questions in dispute being whether certain games were too strenuous for girls, and whether they had any detrimental effect, either immediate or remote, on the organs of reproduction. Players should be of about the same size and strength, but it was difficult to conceive why girls, who had passed a medical test, and who are equal in strength, playing hockey together for an hour should suffer from the effect of too strenuous exercise any more than boys. It must be remembered that an hour or an hour and a half was usually the maximum time that could be spent on the field. The real test as to the over-strenuousness of the game was the condition of the player afterwards, and at Cheltenham the girls returned from the field day after day fresh, vigorous, and with healthy appetites. Dr. Clow asked for the views of school medical officers as to whether children should be allowed to play vigorous games immediately after their meals. Nature did not seem to prompt them to take any interval for rest, as did animals and adult human beings. From her own recollections of childhood and from observations it seemed to her that digestion proceeded just as easily if no restrictions were imposed. As to the effect of games on the organs of reproduction, Dr. Clow had taken special note on the effect of games on the menstrual function in school girls, and found that a smaller proportion of girls suffered from any menstrual disorder among those who played games than among those who did not, and that this small proportion was still further reduced if the usual exercise was continued throughout the menstrual period. For the last eight years she had advised every girl to continue her warm bath and her games, as usual, during the period, if she felt so inclined and had her mother's consent to do so, and a great many, who had formerly suffered from various degrees of dysmenorrhœa, were now entirely free from it. Those who consulted her for dysmenorrhœa were usually elder girls who were reading for examinations, and in their zeal for study had reduced their time for exercise. On resumption of their former daily exercise their symptoms had disappeared. There was a prevalent idea that girls should forgo exercise during menstruation. It was a very rare thing to come across a child who, of her own accord, would give up her games and walks at these times. The "headache" or any other disabling malady, which girls were taught to fake every month as an excuse for not taking part in their usual games, often became a matter of ridicule to their brothers and uninitiated playmates and of embarrassment to themselves, and Dr. Clow regarded restrictions as unnecessary. Dysmenorrhœa was more prevalent among the leisured than among the working classes, and Dr. Clow considered that compulsory work and exercise were the determining factors in their relative freedom from dysmenorrhœa enjoyed by the latter. As medical officer of a students' hostel, Dr. Clow had kept some records of 136 students trained for teaching in elementary schools. The number was too small to form data from which to generalise, but 69 per cent. had been in the habit of playing games as usual throughout the period. Fifteen per cent. of the total number experienced dysmenorrhœa in various degrees. Again, of 734 girls at the Ladies' College, Cheltenham, when only 35 per cent. were playing games during the menstrual period, 23 per cent. suffered from menstrual disturbance, whereas, later on, when, as the result of advice given, 67 per cent. were continuing their games through the period, only 15 per cent. had any menstrual trouble. These latter figures corresponded closely with those obtained at the training college. As to the remote effect of games and gymnastics on pregnancy, childbirth, and the child, Dr. Clow doubted whether anyone in this country was in the position to quote figures of large enough numbers to enable general deductions to be drawn. But she pointed out that coincident with the growing popularity of athletics among girls there had been a diminution in the number of fatalities connected with childbirth and in the rate of infantile mortality. Moreover, centuries had proved that generations of women who hunted had been the mothers of large and healthy families.

Evidence from a Physical Training College.

Miss M. STANSFELD (Bedford Physical Training College) said that in view of the many vague statements made, with no shred of evidence to bolster them up, she proposed to confine her remarks to direct evidence from her own experience. The bulk of the girls coming to a physical training college at 18 years old were among the best in their school at games; yet it was the very rarest thing to refuse an applicant for physical unfitness, except for such things as enlarged thyroid—and though every student had to undergo a probationary term, only two had been rejected from Bedford for health reasons. This was surely evidence that the girls who had played games most came into college uninjured. On entering college the girl began a life that increased her physical work about ten times. Yet the health of students was exceptionally good. Miss Stansfeld said that she made inquiries last year from a hundred girls then in college on the effect of this athletic life on menstruation. In 64 cases there was no pain; in 26 cases pain was said to be slight, and 20 of these said the pain had been lessened by training; in 10 cases the pain was said to be rather bad, but in 3 cases this only occurred in holidays. There was one effect to which she drew attention, and that was on the frequency of the period. In 7 cases menstruation stopped altogether for the first three months, but later established itself regularly; the flow was usually diminished, and in 47 cases the intervals between the periods were lengthened. A rather remarkable unanimity was shown in answer to a question asking what part of the work was affected most by menstruation. A very few felt no difference, but 97 out of the 100 said any work in the gymnasium requiring balance and coördination was adversely affected, and during the whole period their "eye was out" in playing games; they were less accurate and more easily tired; most of them said they were disinclined for games or dancing or gymnastics. Miss Stansfeld therefore did not allow any games or strenuous physical work during the first three days of the period. On July 26th last, at the end of a strenuous term, the hearts of 16 third-year students were examined and were found to be quite normal. To get some idea of the effect of games, &c., on maternity, Miss Stansfeld had sent round a questionnaire to old students who had children, and received answers from 34. She gave details of the answers. In all but three cases the mother had been able to lead her ordinary life up to the day before the baby was born. The answers to the question on health during pregnancy seemed satisfactory, since with the exception of the three cases mentioned the health was described either as "very good" or "excellent." Sixteen stated definitely that they had "no sickness." The third question, on conditions of labour, elicited the fact that 23 had what they described as a very easy time. Miss Stansfeld gave particulars of other cases, in one or two of which labour was prolonged and in two a very rapid delivery was attributed to over-strong abdominal muscles by the nurse only. Recovery in 24 cases was very rapid, normal habits being resumed in from ten days to a month after the birth. There were two cases of slow recovery. The weight and general health of the babies left nothing to be desired.

Discussion.

Dr. E. H. T. NASH (M.O.H., Wimbledon) said that such unadulterated trash had appeared in the lay press on this subject that the excellent papers by

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The opening meeting of this Society was held at 1, Upper Montague-street, London, on Oct. 21st, when Dr. W. J. Howarth, M.O.H. for the City of London, the newly elected President, delivered an address on

Certain Public Health Problems.

After tracing the evolution of preventive medicine from primitive measures of self defence against gross conditions which offended the special senses, through the days of precautions based on experience without scientific foundation, to modern changes consequent upon the development of industrialism, Dr. Howarth pointed out that treatment in adult life meant treatment of conditions which the application of prevention in curative medicine at earlier ages would, in many cases, have rendered unnecessary. The position resolved itself into one in which the two groups of practitioners were not working along parallel lines. The preventive practitioner—that is, the medical officer of health—devoted his chief energies, so far as regards the individual member of the community, to conditions which were discovered mainly below the age of 14 years. The curative practitioner exercised his skill on persons over the age of 16, and under circumstances which did not fill him with enthusiasm for preventive work. A dual organisation therefore appeared to be necessary, curative work, whether in connexion with tuberculosis or venereal disease or such as would be performed by the special departments outlined by the Dawson report, being carried out by a distinct clinical organisation, early preventive work also being arranged for. To carry this proposal into effect the provisions of the National Insurance Act would require to be either extended or altered. Extension would mean the inclusion of dependents, but money was too scarce to expect any such plan to receive favourable consideration. The alternative appeared to him, as a medical officer of health, to require the cancellation of existing arrangements, leaving working persons above the age of 16 to make their own arrangements with doctors, and, if possible, for the State to use the money thus saved to ensure the continuous supervision by practitioners of families in which are children at growing ages.

Dr. F. E. Fremantle, M.P., in inducting the new President, spoke of Dr. Howarth's work extending over 21 years as M.O.H. of Derby, Kent, and the City of London in turn. He had been President successively of the Midland, Home Counties, and Metropolitan branches of the Society.

Prof. H. R. Kenwood proposed a vote of thanks to Dr. Fremantle, the outgoing President. He felt that in the future they would always have his valuable help as a Member of Parliament.—In his reply, Dr. Fremantle said that his year of office had been a critical one, because of the national after-war problems that had arisen, and of the reconstruction of the Society that had been proceeding.

Twenty new members and seven associates were elected at the meeting. A number of candidates were also nominated, arising out of the recent absorption of the Society of Medical Officers of Infant Welfare Centres as the maternity and child welfare Group of the Society of Medical Officers of Health.

MEDICAL WOMEN'S FEDERATION.

The first meeting of the London association was held on Oct. 18th at the Elizabeth Garrett Anderson Hospital. Dr. Louisa Martindale was unanimously elected to the presidency on the retirement of Mrs. Flemming, M.D., and she proceeded to read her opening address on the subject of

Birth-Control.

She pointed out that the movement began in England in 1877 when the Bradlaugh-Besant trial took place. In Germany the movement started later, but once started the birth-rate fell as much in 12 years as it had done in 70 years in France. The fall in birth-rate is, however, accompanied by a corresponding fall in infant death-rate, so that up till now the natural increase in the population had been little affected. Statistics showed further that both birth and infant mortality rates are lower in the more thoughtful and educated classes, and that it is among these classes that methods of birth-control are chiefly used. These methods might be classified as follows:—

1. *Natural.*—Either celibacy or voluntary abstinence, which may be total or during the most fertile part of the woman's monthly cycle.

2. *Methods used by the husband.*—(*a*) Withdrawal or coitus interruptus; (*b*) use of sheath or French letter; (*c*) a dose of X rays.

3. *Methods used by wife.*—(*a*) Quinine pessaries; (*b*) douching; (*c*) introduction of rubber cap.

Of these methods it was agreed that coitus interruptus is bad for the nervous system of both parties. The French letter was the most efficacious—douching and the Dutch cap were not entirely satisfactory.

Dr. Martindale then discussed the views of English Roman Catholic and Jewish churches on the ethics of the matter, and finally summed up the reasons for and against birth-control. Relative poverty, illness during pregnancy or confinement, the possibility of enforced separation should a baby arrive (as amongst Anglo-Indians), disease, such as tuberculosis, inherited insanity, &c., were among the chief reasons given in favour of the practice, whilst risk of encouraging sexual excess and the possibility of eventual sterility were the main reasons against it. The whole aim of the movement was undoubtedly to better the conditions of women's lives. Dr. Martindale thought that there were worthier ways of attaining this end—as, for instance, improved housing, an efficient scheme of employment, as well as educative methods which would help to decrease rather than increase sex excitation.

An animated discussion followed the reading of the paper, and it was decided to consider further aspects of the question in more detail at subsequent meetings of the association.

HEALTH WEEK.

From Oct. 9th to 15th Health Week was observed throughout the country, local arrangements including conferences, lectures, health exhibitions, visits to health centres, and many other activities calculated to rouse public interest in the health of the country. From among the popular lectures given during the week one or two examples may be cited. At Brighton Dr. H. Gervis, J.P., delivered an amusing address on "Bad Health and Good Intentions," in which he discussed the case of an imaginary recruit suffering from numerous ailments and disabilities which might have been prevented by better care in childhood. Thus corns, flat-foot, and ingrowing toe-nails resulted from tight footwear; indigestion from (1) a dose of castor oil administered almost immediately after birth with *a subsequent vicious circle of diarrhœa and constipation, and* (2) eating too much; rupture from too tight application of a "binder" at the same tender age; lung trouble from too much heavy clothing and from a diet containing too little fat; insufficient fresh air and exercise, from a devotion to the kinema and to watching other people play football; and various defects of teeth, throat, eyes, and ears, all derived from causes which might once have been averted. Dr. Gervis remarked, with reference to the neurasthenic condition resulting from these disorders, that he often thought "it would be a great kindness to certain unborn children if people of a highly neurotic nature abstained from procreating their race." At Wakefield, Dr. J. B. McDougall, chief tuberculosis officer of the West Riding County Council, pointed out in a lecture on "Simple Truths Concerning Tuberculosis" that the most difficult problem of propaganda was to make people unlearn false teaching, and instanced the belief, still widely held among the public, that tuberculosis was hereditary. At Poole Dr. R. J. M. Horne, medical officer of health, gave short dinner-hour talks to working-men with great success, pointing out to his audiences that health talks had been given in the schools, and that as the children would doubtless come home and ask questions, it behoved the adults to be able to answer them. Dr. C. W. Saleeby, lecturing at Earl Shilton, Leicestershire, took for his subject "The Light of Day," and discussed the smoke problem of cities and the necessity for a more open-air life for the combating of tuberculosis.

—Mr. TREACHER COLLINS considered that the primary factor was the cyclitis, which had produced a cyclitic membrane. This membrane probably caused an arrest of lymph circulation, which had resulted in the separation of the two layers of pigment at the back of the iris, a cyst being the sequel to that. He advised puncture of the body, which he believed would lead to its collapse.

Dr. WYLIE sent, and Mr. LESLIE PATON demonstrated, a case of Benedict's syndrome. The lesion was supposed to be in the red nucleus, catching the fibres of the third nerve.

The Fourth Cranial Nerve.

Mr. J. HERBERT PARSONS contributed an address on what he termed the riddle of the fourth nerve, the only nerve which had, in the complete sense, a dorsal decussation. It was probable there were no decussating fibres within the central nervous system other than those which passed out in the trunk of the nerve. A peculiarity of the fourth nerve was that it was purely somatic in mammals; it supplied purely somatic muscles and it had no visceral fibres. It was extremely difficult to produce experimental lesions in this neighbourhood sufficiently localised to give definite results. Explanation must therefore be sought in comparative anatomy and embryology. The fourth nerve existed down to the earliest vertebrates, as shown in a slide from a lamprey, in which the eyes were very rudimentary organs. The fourth nerve decussated dorsally, going through the anterior medullary velum in that animal exactly as in the higher vertebrates. Mr. Parsons exhibited slides illustrating the work of Davidson Black, showing the position of the nuclei of the cranial nerves and their points of exit from the central nervous system. The same kind of thing was seen in various specimens of amphibians. Kappers's view was that migration of motor nuclei was due to attraction to foci of incoming afferent impulses (neuro-biotaxis), and the last edition of Sir Arthur Keith's "Embryology" explained the fourth nerve as due to neuro-biotaxis, a view the speaker was sceptical about. Still, there was no doubt of the fact that in the evolutionary process the afferent side became evolved in advance of the motor response. In 1881 Marshall pointed out that in sharks the muscles associated with the third nerve came from the first or pre-mandibular head cavity, the fourth nerve muscles from the second head cavity, and the sixth from the third or hyoid. It was very difficult to obtain evidence of the same thing in the higher mammals. Mr. Parsons pointed out the near association of the fourth and fifth nerves, in the relationship of their branches at a very early stage in their development, and in regard to the ciliary ganglion. Investigation of the transient ganglion of the fourth nerve showed that it did not migrate from the motor part, but developed from the cells of the neural crest. There could be no doubt that this ganglion on the fourth was a posterior root ganglion, and that, at that stage at any rate, the fourth nerve had sensory somatic fibres in addition to motor somatic fibres. Mr. Parsons pointed out that complex synergic movements existed, brought about by nerve nuclei, with fibres which presumably decussated, and which were correlated with each other in a remarkable way in the absence of cerebral hemispheres. Therefore he thought it must be concluded that even at a low stage there was an arrangement for coördinating the synergic movements of the eye muscles. Coördination was usually regarded as entirely cortical, but he thought sufficient stress was not laid on lower coördination centres. This view did not detract from Hughlings Jackson's view, but rather divided that authority's "top storey" into a series of flats.

Mr. ERNEST CLARKE read a paper on

Milestones in Refraction Work

founded upon 40 years of work in the specialty, in which he reviewed the state of ophthalmology in 1881, pointing the great services of Donders in raising the subject of refraction to a scientific level. He said that in eye-strain it was the small errors which counted—i.e., low degrees of astigmatism and anisometropia. Eye-strain might be the "third partner" in any disease; but symptoms attributed to eye-strain might be due to nasal trouble or to dental infection, and extra-ocular conditions should not be lost sight of by the ophthalmologist. If a young person had errors of refraction, the correcting glasses should be always worn, if not at games, always in the house. With regard to myopia the common-sense treatment was to make the patient normal by giving the full correction of the myopia and insisting that the correction should be always worn. With regard to presbyopia, it took years for Donders's teaching to bear fruit. Presbyopes were people who had arrived at a critical stage of life, when there were many worries for them, and in many cases they were the subjects of intestinal toxæmia. Hence every possible channel of waste of nerve energy should be stopped. He proceeded to discuss the subjects of cycloplegics, heterophoria, convergent strabismus, the ophthalmometer, test-types, and trial frames. A short discussion followed.

MEDICO-LEGAL SOCIETY.

A MEETING of this Society was held on Oct. 18th, with Lord Justice ATKIN, the President, in the chair, when Mr. VALENTINE BALL, Barrister-at-Law, read a paper on

INCAPACITY FOR WORK WITHIN THE MEANING OF THE NATIONAL INSURANCE ACT, 1911.

He said: Since the National Health Insurance Act, 1911, it has constantly to be decided whether an insured person is capable of work. This question is decided by a committee of the society of which the insured person is a member. But there has always been a right of appeal. Cases are now heard by a referee and two assessors appointed by the Ministry of Health; the referee is generally a barrister-at-law and one of the assessors a medical man. The National Insurance Act, 1911, confers "periodical payments to the insured," whilst rendered incapable of work by some specific disease or by mental or bodily disablement continuing for a period not exceeding 26 weeks (sickness benefit); also in the case of disease further payments at the termination of sickness benefits (disablement benefit) so long as the subject is rendered incapable by the disease or disablement. Mr. J. H. Watts, in his work on National Insurance, gives it as his opinion that disablement benefit could only be given when the insured was totally incapacitated from doing any work. The decisions of the court—that is, the referee and his two assessors—make it quite plain that the insured person is not entitled to benefit merely because he is rendered incapable of doing the work at which he was employed when the sickness or disablement supervened. Thus, in a case decided in October, 1915, a man who combined the occupation of iron-ore miner with that of lodging-house inspector under an urban district council, and was admittedly unable to carry on the former occupation on account of bronchitis, was held to be not "incapable of work" within the meaning of the Act, since he had been able to carry on the duties of the latter post, partly himself, and partly by deputy. On the other hand, decisions of courts show that "the mischief at which the Act aims being the loss of wage-earning capacity through illness, the question of capacity for (any kind of) work cannot be regarded in the abstract without reference to the particular circumstances of the insured person concerned." It is, however, held to be the duty of an insured person to make an attempt to work if there is medical evidence to show that such attempt will not be prejudicial to his health. In one instance a man suffering from spasm of the œsophagus was suspended from receiving disablement benefit on the ground that, in the opinion of his society, and of its medical advisers, he would be better at work. The patient imagined that he was suffering from cancer. The court, however, found in the stool, nor that Bilharzia enters the human body in the form of a cercaria which penetrates the skin while people bathe or wade in water. The parasite of malaria and its carriage by the mosquito are dealt with in a sufficiently explicit manner, but the omission of any mention of the mosquito-net, the most important of all prophylactic measures with which a nurse has to do, is to be regretted. The section devoted to the consideration of vegetable parasites is clearly presented. It might be improved if greater emphasis were laid on the methods of infection. It is of the utmost importance that nurses should understand the dangers of infection in dysentery and typhoid, and clearly grasp the fact that the stools of such cases are swarming with bacteria, which may easily be transferred on the hands, utensils, or food to other individuals.

The book, which has two attractive plates, is undoubtedly useful and should help those for whom it was written better to understand many of the routine methods adopted for the handling of infectious patients.

NEUROLOGY.

The Form and Functions of the Central Nervous System. An Introduction to the Study of Nervous Disease. By FREDERICK TILNEY, M.D., Ph.D., Professor of Neurology, Columbia University; and HENRY ALSOP RILEY, A.M., M.D., Associate in Neurology, Columbia University; with a Foreword by GEORGE S. HUNTINGTON, Sc.D., M.D., Professor of Anatomy, Columbia University. London: H. K. Lewis and Co. 1921. With 591 figures containing 763 illustrations, of which 56 are coloured. Pp. 1020. £3 10s.

THE two American neurologists responsible for the production of this handsome volume have undoubtedly deserved well of the profession both as regards their detection of a lacuna in neurological literature and their effort to fill it. There always comes a time in the development of neurological knowledge on the part of the student or physician who is taking his subject seriously when he finds that he must know more nervous anatomy and more neuro-physiology. No amount of easy clinical acquisition derived from the observation of a large number of more or less similar cases—as occurred on a huge scale in the war in reference, e.g., to "shell-shock"—can in any degree compensate for anatomo-physiological ignorance of the nervous system. No study of mental disease, howsoever abundant the clinical opportunities, can be anything but incomplete if it is not erected on the fundamental basis of acquaintance with normal neural function. If the same mechanisms, physiological or psychological, are in activity in disease as in health, he neglects an essential factor in his comprehension of the former state who fails to make himself conversant with the processes of the latter. For the neurologist the detailed and comprehensive treatise of Dr. Tilney and Dr. Riley is practically a sine qua non. Within its boards he will find collected, organised, and clearly set out a body of doctrine, anatomical and physiological, which is, in the simple meaning of the word, indispensable; and its application to clinical medicine is throughout borne in mind, so that data otherwise relatively uninteresting or unimportant if detached from this application become meaningful and are seen to fit into the neurological scheme.

Merely to indicate the contents of a volume which runs to a thousand pages would occupy too much space in a brief review. The book consists in reality of several treatises, on nervous embryology, anatomy, physiology, pathology, and on clinical neurology. It is nothing if not ambitious. Take a single example—the cerebellum; in successive chapters its evolutional significance, its relations, surface appearance and anatomy, its internal structure, histology and embryology, its functional significance, its principal syndrome and its variations, are handled with ability and are admirably illustrated. This all-embracing plan of description is adopted throughout for all the components of the nervous system. There are various imperfections, only one or two of which can here be indicated. Thus the question of tonus and its modifications is dealt with in a scattered and incomplete fashion, and, as far as we have noted, there is no correlation of the disorders of tonus arising from lesions in various widely differing parts of the neuraxis. There appears to be no systematic description of the tendon reflexes, and ankle clonus is not to be found in the index; Babinski's plantar reflex is included under abnormal associated movements and is mentioned elsewhere in passing, but is not apparently described. Nystagmus is baldly stated to be the result of disturbance in the synergic units controlling the eye movements, but its importance as an organic symptom would have justified discussion at much greater length. The work is stronger on the anatomo-physiological than on the clinical side, but it does not pretend to be a complete text-book of semiology. A useful glossary, a bibliography, and an index running to more than 40 pages add to the value of a treatise which is a credit to American neurology, and which will at once take its place as a volume of reference.

SYPHILIS.

A Treatise of Ætiology, Pathology, Diagnosis, Prognosis, and Treatment. Section I. By Dr. H. H. HAZEN, A.B., M.B., Professor of Dermatology and Syphilis, Georgetown University, Washington, D.C. London: H. Kimpton. Pp. 647. 42*s*.

IN his introduction to this work Dr. Hazen states that "there exists no small book that covers the whole field of syphilis in an authoritative way." The statement is true. There are many voluminous tomes and there are many smaller works devoted to this subject. There are also sections in many books which, dealing with venereal disease as a whole, necessarily include syphilis. The voluminous tomes are too bulky, and the smaller works, useful as they may be to the elementary student, are not sufficiently wide on the one hand or definite upon the other to satisfy the requirements of the practitioner or advanced student. This volume is useful in that it not only gives a general sense of perspective but also deals with the subject of syphilis in respect to its more specific manifestations, affecting the special senses and the endocrine glands. After reading this book a general practitioner will not necessarily be in a position to undertake entire charge of patients suffering from every syphilitic manifestation, but at least his clinical horizon will be so developed as to enable him to know when expert aid should be invoked. The author protests against empirical and routine reliance upon the bacteriological and serological measures, which are only to be regarded as being adjuvants to clinical observation.

Dr. Hazen is unduly optimistic in his presumption that his readers possess an adequate knowledge of dermatology. Unfortunately, a large number of those responsible for the treatment of syphilis do not possess that knowledge of skin diseases which should be a preliminary to a practice involving the care of syphilitic cases. We should also be glad to see in a future edition a warning that the Wassermann reaction should only be carried out by those in constant practice. Chapter XV., by Dr. H. A. Fowler, on Syphilis of the Genito-Urinary Organs, is especially useful, though but little information is given in respect of the diagnosis of syphilitic lesions of the cervix. In the chapter devoted to syphilis of the nervous system by Dr. J. E. Lind, the section on neuroses is particularly enlightening. We regret that, possibly owing to considerations of space, more discussion of the problems of the prevention of syphilis by either medical or sociological means has not been included.

While congratulating Dr. Hazen and his colleagues upon their achievement, we may hope that on the appearance of a second edition we shall also be able to congratulate the publishers upon providing a binding of stability more worthy of the valuable material which it includes.

but only during that time; for the gradual acclimatisation of the insured subsequently warranted a reduction of the insurance rate. The most common causes of ill-health in the tropics were malaria and dysentery, which frequently invalided but comparatively seldom killed. Consequently the extra premium for insurance against death, he held, was not justifiable. He maintained that the statistical returns of companies issuing life insurance policies in the tropics were based on inexact reports, which gave an unfounded character of deadliness and additional risks to certain climates. Such returns were of little real value unless dependent on the reliable data of the resident medical men, who should be appointed to act as registrars. He asked pointedly whether the candid experience of the medical officers of the societies concerned bore out the statistics drawn up by the actuaries. Actuarial details of the insurance companies gave no information as to disease in the tropics, and the true particulars could only be obtained from medical men in the various countries affected. The injustices imposed by the high insurance rates were in part due to evils of red tape, hide-bound rule of thumb methods, and mechanical organisation which prevented a readjustment of the companies' rules to meet the present-day experience of the improved conditions of life in the tropics, and in part to the barrier offered by the combine of the insurance companies which opposed any reduction of premium. He instanced as an example of the paradoxical lack of equity in the insurance rates the case of an Anglo-Indian whose ill-health in England was only remedied, and his life prolonged, by a return to India. Yet, so long as he stayed in England, where it was risking life to remain, he paid a lower premium than he did in India, where conditions were more favourable to a maintenance of health. He had come to the conclusion that a just and fair remedy would be to reduce the extra premium, after a period of acclimatisation in the tropics of four or five years, on provision of a clear medical certificate; or, avoiding the extra premium altogether, the value of the policy might be reduced in the first years from, say, £1000 to £750, and subsequently raised to the full sum insured. He also referred to the readiness with which American companies were eager to insure life in the tropics at a lower rate than British companies.

Discussion.

Sir William Leishman felt sure that statistics were available to show that the risk attaching to young men going out to the tropics was greatly exaggerated, and that their publication should serve to relax the stringency of the additional insurance rate.

Sir Leonard Rogers drew attention to facts, which insurance companies seemed disposed to ignore—namely, that as the result of modern advances in tropical medicine conditions of living in the tropics had been much improved (e.g., antityphoid inoculation), the danger of typhoid fever had very largely disappeared, and by present methods of treatment death-rates from cholera, liver abscess, and dysentery had been greatly reduced and the risks to life and health much diminished. It was only right that such facts should be brought home to the insurance companies with a view to lowering the extra premiums charged for the tropics. He could confirm the President's reference to the activities of American agencies and their readiness to circularise their branches with information based on statistics of disease in the tropics.

Several subsequent speakers quoted their experiences of tropical insurance rates. In some instances no additional premium had been imposed by residence in the tropics, the policies being world-wide; others, less fortunate, however, had been obliged to pay a higher rate. In one case this amounted to an addition of 4 guineas per cent. of the total insured, and that only for transference from Northern Rhodesia to Tanganyika territory.

The President, in the course of his reply, sought explanation as to how far the frequency of leave demanded by the West African Service was due to the influence of climate or actual disease contracted on the West Coast, and referred to the prohibitive rates charged by shipping companies for the passage home of invalids as an evil which needed remedy. He suggested the advisability of the Society appointing a committee to inquire into the whole question of tropical life insurance. It was, he maintained, a matter in which the Society might well act in an advisory capacity and as referees.

On his proposal being put to the vote, the opinion of the meeting proved to be evenly divided.

Demonstration and Short Papers.

A demonstration was given by Dr. J. G. Thomson of the transmission of *Trypanosoma cruzi* by the bug *Rhodnius prolixus.* Living specimens of the male and female reduvid bug, *Rhodnius prolixus*, were shown which had been hatched out five months previously from ova sent from Venezuela by Dr. Henri Tjera. The bug, measuring about ½ inch in length, was common in South America, and infested the burrows of the armadillo, but readily bit other animals and human beings. The armadillo was regarded as a possible host of *T. cruzi*, transmission being effected through the agency of the parasitic bug. The specimens shown of *Rhodnius prolixus* had been fed on a young rat infected with *T. cruzi*, and the fluid dejecta of the bugs contained the living trypanosomes. The demonstration included microscopical specimens of (1) the recent secretion of the bugs exhibiting actively moving forms of *T. cruzi;* (2) stained films of the bug's secretion containing the trypanosomes; (3) stained section of the heart muscle of a rat infected with *T. cruzi* by intraperitoneal injection of the secretion of *Rhodnius prolixus*, showing trypanosomes in the muscle-fibres, where they had apparently curled up and assumed leishmania-like forms; (4) stained films from the blood and heart muscle of the infected rat showing *T. cruzi* in both the crithidial and fully developed stages; (5) flask-shaped ova of *Rhodnius prolixus* with their flap-like lids.

Dr. C. M. Wenyon, hon. sec., communicated an abstract of the following short papers which had been presented for publication in the Society's Transactions: (*a*) Note on Relation between Tsetse-Fly (*G. morsitans*) and Game in the Proclaimed Area Nyasaland. (*b*) History of the Introduction and Spread of Human Trypanosomiasis (Sleeping Sickness) in British Nyasaland in 1908 and following Years, by Dr. W. A. Murray (late Captain S.A.M.C. and Officer-in-Charge of Sleeping Sickness Investigation in Zululand). Sleeping sickness, usually transmitted by *G. palpalis*, had been introduced into Nyasaland in 1908 in the form of *T. gambiense*, and its excessive virulence there was ascribed to transmission by the tsetse-fly, *T. morsitans.* (*c*) A note on the Treatment of Suppression in Blackwater Fever, by Dr. A. F. Wallace (Medical Officer, Northern Rhodesia Administration), drew attention to the relief afforded by high rectal irrigation with hot saline injections. (*d*) A preliminary note on the Development of *Loa loa* (Guyot) in *Chrysops silacea* (Austen), by Dr. and Mrs. A. Connal, of the Medical Research Institute at Lagos. Since their previous communication[1] to the Society these workers had confirmed the important results of their earlier research on *Chrysops silacea* as the host of *Loa loa* by a number of experimental investigations of the feeding of infected chrysops on guinea-pigs. The reluctance of the infected fly to feed, which had been observed, was attributed to the obstruction caused by the presence of the filarial embryos in the fly's proboscis. It was noted that the fly endeavoured to free itself by milking the blocked proboscis with its forelegs; in the course of this process small masses of embryos were flicked off and could readily be seen by means of the microscope on the skin of the subject fed upon.

osteitis fibrosa.—Sir Gilbert Barling publishes a series of 100 operations for gall-stones in private patients, referring specially to cases in which there was a recurrence of stones. He concludes that cholecystectomy is the operation of choice.—W. C. B. Meyer describes a case of the Klumpke type of upper limb palsy, caused by a cystic enlarged first rib. In addition to the bony lesion, there was a soft swelling in the subcutaneous tissues just above the left clavicle, and X rays revealed a second tumour close to the apex of the left lung. Operation relieved the symptoms and established the diagnosis of hydatid disease of the bone.—Valentine St. John describes four recent cases of tuberculosis of the flat bones of the skull, and suggests that the two generally accepted varieties are really only stages in the same process. He discusses the disease in all its aspects, emphasising the need for radical treatment.—Sir George Lenthal Cheatle continues his contribution on cystic changes in the breast; in this one he establishes a connexion between cystic and epithelial changes on the one hand, and the development of benign and malignant new growths on the other.—Sir W. I. de Courcy Wheeler records a successful reconstruction of the knee-joints in a girl aged 8. She had had acute osteomyelitis in both tibiæ, which resulted in bony ankylosis, on one side in marked flexion. A Murphy's arthroplasty was done on each knee with good results. He also gives an account of the reconstruction of a much damaged shoulder. The acromion, the deltoid, and the upper half of the humerus were missing, due to a wound. The loss of bone was repaired by a graft from the tibia, the loss of muscle and skin was overcome by transplanting the clavicular head of the pectoralis major and by a skin flap from the chest.—A. H. Burgess publishes a case of broncho-biliary fistula.—H. Poston gives details of a case of traction fracture of the lesser trochanter of the femur, which makes the twenty-fourth case recorded.—The operative treatment of closed fractures of the long bones by metal bands is discussed by E. G. Stanley and J. Gatellier, and details of a new instrument, devised by the latter, are given.—Accounts of visits to the clinics of Dr. Hugh Hampton at the Johns Hopkins Hospital, and of Sir Harold Stiles at Edinburgh are given.—G. G. Armstrong records a rare anomaly occurring in two patients, consisting in the absence of a mesentery for the terminal six inches of the ileum.—T. H. Kellock summarises the advantages of a two-stage operation in cleft palates.—The last part of the journal deals with instructive mistakes and notes on rare and obscure cases.

To the October number of the British Journal of Experimental Pathology L. Hill and J. McQueen contribute a paper, entitled Capillary Blood Pressure Measurement and the Glomerular Filtration Theory, which deals with the modern theory of the secretion of urine; evidence is brought forward to show that pressure in the glomerular capillaries is a low one, and that physiological permeation—not filtration—controls the passage of fluid through the glomeruli. Observations on the circulation in the frog's glomeruli are detailed and support these conclusions, which are also borne out by experiments of H. J. Hamburger demonstrating the selective action of the epithelium covering the glomeruli.—J. O. W. Barratt writes on the Theory of Agglutinin Estimation.—S. Yabe contributes an account of the Preventive Effect of Influenza Vaccine. In our statistics, he says, by the use of the heated influenza vaccine, the morbidity of those inoculated was reduced by a half as compared with the rate of those uninoculated. In other statistics, in which the inoculation was begun just at the commencement of the epidemic and was finished at its acme, this morbidity among the inoculated persons, as compared with that among the uninoculated, was reduced to one-sixth by the use of the vaccine. The complications from catarrhal pneumonia were lessened in the case of inoculated patients to one-half and deaths to one-seventh. The length of fever was less among the inoculated persons in proportion to the quantity of vaccine inoculated. The reaction after the inoculation was so slight that cessation from work was unnecessary.—J. Pratt-Johnson describes Comparative Immunity Tests with Saline Vaccines and Lipovaccines. (1) Lipovaccines prepared and employed in the manner described stimulate the production of agglutinins to a lesser degree than saline vaccines administered in the same doses. (2) The presence of a high titre of agglutinins does not necessarily indicate the presence of an established immunity even against small doses of a highly virulent organism. The same author, in Further Studies on the Production of Immunity in Rabbits against an Organism of High Virulence for the Species, describes experiments which demonstrate the possibility of securing the immunity of rabbits against an organism of high virulence by immunisation with a live related organism avirulent for the species. In this respect, Tenbroeck's observations are confirmed, and it is further shown that killed vaccines, prepared either from the homologous or from a related organism, fail to give solid immunity against the live virulent strain.—I. Walker Hall and A. D. Fraser discuss the pH Range for Staphylococci. The general pH range for the staphylococcal group extends from pH 2·6 to pH 10. But individual or group variations occur which do not exhibit any relation to saprophytic or pathogenic characters.

St. Bartholomew's Hospital Journal.—The October issue is in the main a freshman's number, for most of the matter is concerned with impressing upon those who are entering upon their medical career the importance of the work which they have undertaken, the difficulties thereof and how they should be met, and the fact that St. Bartholomew's Hospital is the best hospital in the world. Other hospitals think the same, and it is well that they should do. But St. Bartholomew's has at least one asset which no other hospital in the Empire has, with the exception of that dedicated to the same saint at Rochester—namely, a record of eight hundred years. The paper entitled "The Making of a Doctor," written from four points of view by four men of experience and distinction, is full of sound sense. The school is to be congratulated upon having obtained a Royal Charter of Incorporation, the text of which is given in full.

The current issue of the Journal of the Royal Naval Medical Service opens with a paper of great interest on eight cases of infection by *Schistosoma japonicum*, by Surgeon-Commander A. A. Sanders and Surgeon Lieut.-Commander J. L. Priston. The cases were contracted through wading in marshes during shooting expeditions in the Yangtse Valley. Clinically they were characterised by pyrexia (in one case lasting three weeks), urticaria, serious loss of weight, and eosinophilia. Ova, without any spine, are found in the fæces only. Antimony tartrate appears the most encouraging treatment.—Surgeon-Commander G. O. M. Dickenson writes on venereal disease in the eighteenth century, his text being a book by N. D. Falck, surgeon, 1772, who recommended mercurial ointment and a calomel injection as prophylactics, saying: "If I am blamed for this openness; I answer in my defence; my talk is to endeavour to do good: I cannot prevent abuse." The present instalment of the naval medical history of the war concerns the hospital ships.—Surgeon-Captain F. J. A. Dalton gives a detailed account of the treatment of the wounded who came from Gallipoli, and emphasises the need in a hospital ship for large well-ventilated theatres such as he had in *Rewa*. Surgeon-Commander A. R. Fisher tells of the hospital yacht *Liberty* attached to the Dover patrol. Excision of wounds appears to be less necessary on board ships. He found irrigation with Dakin's solution less satisfactory in *Liberty* than it had been in *Rewa*, but in *Rewa* the solution had been made up by Dr. Dakin himself.—Surgeon-Commander L. Kilroy recommends the immediate treatment of syphilis on board ship rather than in hospital.

Reviews and Notices of Books.

PARASITOLOGY.

The Intestinal Protozoa of Man. By CLIFFORD DOBELL, M.A., F.R.S., Protistologist to the Medical Research Council, National Institute for Medical Research, London, and F. W. O'CONNOR, M.R.C.S., L.R.C.P., D.T.M. & H., Wandsworth Scholar, London School of Tropical Medicine. London: John Bale, Sons and Danielsson, Ltd. 1921. Pp. 211. 15s.

IN an earlier publication Mr. Dobell dealt in detail with the human intestinal amœbæ. Now, in collaboration with Dr. O'Connor, he considers the whole subject of the intestinal protozoology of man, treating it in that same lucid, critical, and practical manner which characterised the earlier work. As a practical guide to the diagnosis of the various protozoa which inhabit the intestinal canal of man this book will undoubtedly fill an important place.

During the war a vast literature dealing with this special branch of human parasitology has accumulated. Any attempt to deal with these records is rendered the more intricate on account of the fact that many investigators who have published their views were approaching the protozoa without the previous knowledge and experience essential to accurate records and deductions. The whole of this war literature, as well as that of the pre-war period, has been carefully considered by the authors. That which can be reliably accepted has been sifted from the mass of ambiguous and erroneous statements, and has been presented to the reader as a most interesting narrative. The student may accept the volume with the assurance that he will not be misled and that he will find in it everything that is actually known about these protozoa—their mode of life and reproduction, the methods of their dissemination, their distinctive characters, their pathogenicity, and the drugs which affect them adversely, and which in consequence are used in the treatment of the diseases they produce.

After an introductory chapter dealing with the protozoa in general, their position in the animal kingdom, and their classification into various types, the authors pass on to consider the five species of the intestinal amœbæ of man, of which *Entamœba histolytica* alone is pathogenic. The important question of the carrier of this amœbæ, first brought to light through the investigations of E. L. Walker in the Philippines, is discussed in some detail. Chapter IV. is devoted to the intestinal flagellates of man, of which the authors admit five authentic species. In their opinion there is as yet no good evidence to prove that any intestinal flagellate found in man is pathogenic; on the contrary, the evidence suggests that most and probably all of them are harmless. In this opinion they differ from many clinicians who believe that in certain cases the flagellates are definitely harmful, though the absolute proof of this is difficult to obtain. The various coccidia occurring in man are next considered, the life-history of a typical coccidium is explained, and its method of destroying the intestinal epithelium is illustrated by a diagram. Human coccidiosis, as far as is known, is a transient condition, so that the extensive destruction of epithelium which occurs in heavy infection in animals is not seen in man. Of the three ciliates of the human intestine *Balantidium coli* appears to be the only one of practical importance, since it gives rise to balantidial dysentery much in the same way as *E. histolytica* produces amœbic dysentery. Carriers of *Balantidium coli* also exist, and the relationship of the human infection to that which occurs in pigs and monkeys is discussed by the authors.

In Chapter VII. are described the methods employed for diagnosis of the intestinal protozoa and the many pitfalls which beset the path of the unwary. If the instructions given in this practical section are carefully followed errors of diagnosis will be reduced to a minimum. The authors point out that no protozoologist will ever venture to diagnose an infection without actually seeing the particular organism. In this connexion various "clinical makeshifts," such as the character of the stool, its cellular constituents, and Charcot-Leyden crystals, are discussed. According to the authors, none of these lead to anything more than "plausible guesses" as to the nature of the condition present. They perhaps do not sufficiently recognise the fact that in certain cases the treatment of a patient has to be begun before an accurate diagnosis by the discovery of the parasite can be made. Furthermore, there is always the danger that the discovery of such a parasite may actually lead to an erroneous conclusion as to the cause of the illness. No one would withhold emetine in a case of hepatitis because amœbæ could not be discovered in the stool, and it would be quite unnecessary to administer emetine to a case of acute bacillary dysentery or malaria even if *E. histolytica* were present in the intestine. It is perhaps unfortunate, though unavoidable, that clinical diagnosis is in such cases a guess. The protozoologist may be able to assert that such and such an organism is present, but whether the symptoms of any particular case are actually due to the organism or not can often be decided only by the success or failure of special lines of treatment.

In Chapter VIII. the various treatments which have been recommended for intestinal protozoal infections are reviewed. Of the numerous medicaments which have been employed emetine and ipecacuanha hold first place and it would appear that these alone have any specific action. Curiously enough, emetine gets rid of infections of *E. histolytica* and *Iodamœba bütschlii*, two amœbæ of very different habits, though the other intestinal protozoa are not affected. In the last chapter a number of coprozoic protozoa are dealt with. These are free-living forms which produce resistant cysts. The latter are frequently ingested with food and pass unharmed through the intestinal canal. Soon after the stool has been passed these protozoa emerge from their cysts and commence multiplying, so that erroneous impressions as to their being parasites of the intestine are readily obtained.

The book is well illustrated with a series of eight plates and text figures. One plate deserves special mention, since it is bound to be of particular value in diagnosis. In this plate the appearance of a hypothetical cyst of each protozoon is shown under three conditions—in simple saline solution, in iodine solution, and stained by the iron-hæmatoxylin method.

The book should be read by every student of this highly specialised subject. It is the only up-to-date account of the human intestinal protozoa which exists, and the authors are to be congratulated on having presented to the scientific world such an excellent treatise.

Elementary Parasitology. (First Year.) By THOMAS T. O'FARRELL, F.R.C.S. Irel., D.P.H., President, Section of Pathology, R.A.M.I.; Pathologist, St. Vincent's Hospital, &c. Dublin: Fannin and Co. 1921. Pp. 32. 1*s*.

THIS little book has been written expressly for nurses, with a view to giving them some idea of the numerous parasitic diseases with which they come in contact in their professional duties. There are two sections, the first dealing with Animal and the second with Vegetable Parasites. The various ecto-parasites, such as the flea, louse, and itch-mite, are briefly described and the part they play in the carriage of disease is simply explained. The louse as a carrier of typhus fever is mentioned, but its transmission of relapsing fever is omitted.

Endo-parasites like the tape-worms, flukes, and round-worms are next considered. Though the method by which people become infected with tape-worms is described, there is no mention of the fact that Ascaris and Oxyuris gain entrance to the body by the eggs of the employers, while offering little temptation to the employed, was altogether unacceptable to the Irish National Party, and it was by a compromise with this opposition that the Government consented to remove the medical benefit from the Bill in its application to Ireland. The medical profession, though it made no formal decision on the point, was, on the whole, in favour of the Bill being the same for Ireland as for Great Britain. The medical benefit not applying in Ireland, it might have seemed that the medical profession would have no further concern with the Act, but it speedily appeared that their coöperation was necessary. For the administration of the sickness benefit medical evidence of incapacity was required, and the profession on this point made two demands: (1) that the evidence should be a certificate from the insured member's medical attendant, (2) that there should be provision for adequate payment for certificates. It is not necessary to go into the details of the bitter triangular struggle which lasted for nearly three years between the medical profession of Ireland, the officials of the approved societies, and the Irish Insurance Commission, before the points demanded by the profession were finally granted. Since the beginning of 1916 a scheme for the provision of evidence of incapacity has been in operation which, on the whole, has given substantial satisfaction to all parties concerned. The certificate of the medical attendant is accepted as evidence of incapacity, subject to appeal under certain conditions.

It will be seen, therefore, that whereas a panel practitioner in Great Britain is concerned under the Insurance Acts to supply treatment to insured persons and to give evidence of their incapacity, his confrère in Ireland is only concerned with the giving of evidence of incapacity. The position has failed to give satisfaction either to the medical profession or to the insured. The latter fail to see why they are left unprovided with the medical attendance which is given to their fellow-members in Great Britain. They resent the implication that they should make use of the Poor-law system, and be compelled to plead their poverty to obtain what insured persons in Great Britain receive as a right. They have persistently demanded that the medical benefit should be provided in Ireland as in Great Britain. The heads of the large societies, which operate in both countries, have pointed to a higher incidence of sickness among their members resident in Ireland than among those in Great Britain, and they have assigned the absence of the medical benefit as the cause of this higher incidence. The demand for the provision of medical benefit in Ireland was made with great force by the representatives of the Approved Societies to the Irish Public Health Council in 1919-20, although they were willing to consider other methods than the panel system of providing medical attendance in Ireland, should special conditions render some other system more convenient. Turning to the medical profession in Ireland, it has been equally dissatisfied. It has deplored the imperfections of the system of medical attendance under the Irish Poor-laws as degrading to the working classes, and owing to the conditions of service, equally degrading to the medical practitioner. But there has been a sharp difference of opinion as to the best policy to be adopted. In the industrial areas in and near Belfast the demand has been for the panel system as it is in Great Britain, leaving Poor-law reform aside as a separate problem. But the country doctors generally, and the great bulk of the profession throughout Ireland, thought that the two problems should be dealt with together, and urged as a solution the establishment of a part-time National Medical Service which should provide treatment both for the "poor person" and for the insured, the latter contributing as in Great Britain. This scheme found favour with the Irish Public Health Council, which, in its report published more than a year ago, urged the establishment of such a Service. No steps were taken by the Government to carry the advice of its Health Council into effect. It is likely, however, that when a legislature is effectively established in Ireland, reform will follow the general lines of the report of the Irish Public Health Council. At any rate, the working classes are not willing to rest content without the provision of medical treatment on a contributory basis and free from any taint of pauperism.

◆

Methods of Contraception.

THE publicity given to Lord DAWSON's address on the practice of birth control emphasises once again the immense importance attached by the public to medical opinion on this subject. Lord DAWSON spoke chiefly on the ethical and sociological aspects of the subject. The opinions he expressed will be shared by many of his colleagues in the profession; many would go farther and some would go less far. But, as we have pointed out, any practitioner is liable to be drawn into a discussion on the propriety of the artificial prevention of conception in certain given circumstances, and if he will not or cannot answer a definite question on the relative merits of different methods, the patient may be driven into hands less scrupulous and also perhaps less judicious.

The fact is that, contrary to a public impression, the doctor is not familiar with the scientific aspects of the subject, which have not as yet been thoroughly worked out, and there is no easily accessible medical literature pointing out the advantages and disadvantages of the various methods of contraception in current use. In THE LANCET recently we set forth the present position in the following words:—

> No part of the medical curriculum deals adequately with the applied anatomy, physiology, and pathology of the reproductive system. In certain physiological text-books detailed consideration of this system is omitted; in others it is disposed of in a brief chapter. Few teachers discuss openly and clearly with students the genesis, the psycho-physiological significance—with due reference to reaction time in either sex—of the sexual orgasm. Later on the gynæcologist is more concerned with the retained products of conception than with its prevention, and the venereal expert with problems of infection rather than human and social problems. And yet not only the gynæcologist and the venereal expert, but the neurologist and the alienist are daily concerned with the end results of the sexual life of the patient. Not only the ethics of the control of parenthood, but the less undesirable methods of control should be familiar to the profession; the public is prepared to turn to the doctors for guidance, and it is not the fault of the public that doctors are ill-equipped to give it. Even the subjects of impotence and abortion are better understood, though chiefly from the medico-legal standpoint. But any qualified doctor should be placed in a position to inform first himself and then, at his discretion, his inquirer, firstly, of the arguments for and against contraceptives, and secondly, of the relative degree of nervous wreckage to be anticipated from the use of any one method.

There is as yet nothing to be added to these generalities. The interest aroused by Lord DAWSON's courageous address makes the gap in medical knowledge a very noticeable one, and steps are already being taken at least to take stock of the present position. The Federation of Medical Women chose this subject for consideration at their first meeting of this session, which we report on p. 908 of our present issue. The Medical Council of the Federation of Medical and Allied Societies are discussing the question, and no

V.R. 76: A FRENCH MILITARY HOSPITAL.

By HAROLD J. RECKITT. London: William Heinemann. 1921. Pp. 292. 21s.

BOOKS dealing with war hospitals are always interesting although they naturally have a strong resemblance one to another. But the record now before us is remarkable in that it describes a military hospital practically founded and financed by one who, though himself a Quaker, had no scruples in doing what he could to help the fighters for freedom and justice. Mr. Reckitt tells us in his earlier chapters how he and his wife determined to do something more than give money; they were in the happy position of being able to do this, but as he says "giving without working seemed to my wife and myself an empty thing—we had to find out what we could do ourselves." So they determined to start a hospital in which they themselves could work, helped by inhabitants of their own village who were too old for army service. There were many difficulties in the way of realising this idea, and finally Mr. Reckitt went into partnership with Lady Johnstone, wife of Sir Alan Johnstone, British Minister at The Hague, who was also trying to found a hospital. Eventually a start was made in a disused Marist College at Ris Orange, about 20 miles from Paris on the Fontainebleau Road. The staff was mainly British and American, though there were also members of other nationalities, including French, Italian, Russian, Dutch, Norwegian, Luxemburg, Filipino. The hospital got under way about July, 1915, and continued its beneficent work until 1918, in September of which year it was moved to Juilly. This date concludes the first part of the book written by Mr. Reckitt; Part II. consists of chapters contributed by various members of the staff, written from their particular point of view.

The motto of Verdun, "They shall not pass," was the spirit which inflamed the Allies with that force which enabled them to win through, and although the Johnstone-Reckitt Hospital was but one, and that a comparatively small one out of many, its record shows a spirit of which its founders may well be proud.

PRACTICAL CHEMICAL ANALYSIS OF BLOOD.

By VICTOR CARYL MYERS, M.A., Ph.D., Professor of Pathological Chemistry, New York Post-Graduate Medical School and Hospital. London: Henry Kimpton. 1921. Pp. 121. 10s.

NOT only does blood analysis yield information of value in such conditions as diabetes mellitus, nephritis, and gout, but its sphere of usefulness is being extended daily to a variety of diseased conditions. That this is so is due primarily to the labours of American workers using the methods which they have themselves devised. The result of all this work has tended to show that the chemical analysis of the blood yields results of far greater value to the clinician than can be obtained from repeated urinary analyses. The American journals of recent years have been occupied by papers dealing with methods of estimation of various blood constituents, modifications of the methods, criticisms of reagents employed, and also with detailed accounts of the results obtained. It appears abundantly evident that methods in the hands of those who have devised them prove successful, but it does not follow that equally successful results are obtained by other workers using the same method. Much depends upon confidence in the reagents and apparatus employed. A useful feature of Prof. Myers's book is that a list of standard solutions and reagents is provided at the end. Careful directions are given for the preparation of the reagents employed in the text, and the frequent use of the words "pure" and "of the highest purity" is to be commended. In dealing with small quantities of blood it is necessary to use good reagents, and to obtain results with the minimum of error it is advisable to carry out the estimations in a well-equipped laboratory.

The book was designed as a brief survey of the subject of blood analysis for physicians and laboratory workers. Only those methods of analysis employed by the author are given in detail, with illustrations of particular types of apparatus used. Other methods might with advantage have been included, particularly those of Folin and Wu. The reasons for carrying out estimations of certain blood constituents are closely defined, and the results portrayed in the form of useful and clearly printed tables. A perusal of the methods given in this book will show that the technique is complicated and requires considerable practice before conclusions can be drawn from the results obtained. Exception may be taken to the term "renal diabetes" as giving rise to an entirely wrong conception. There is a distinct group of patients suffering from mild glycosuria without any of the clinical manifestations of diabetes mellitus. The condition is non-progressive, and needs no restriction as regards diet. A satisfactory diagnosis can only be made by an estimation of the blood sugar, which is invariably normal or subnormal. These patients are unfortunately labelled as "renal diabetes," when they present no evidence of renal insufficiency apart from the fact that their kidneys leak sugar, and they are not suffering from diabetes. Besides these there is a distinct type of parenchymatous nephritis with mild glycosuria and slight hyperglycæmia, which is included by Prof. Myers in the group of "renal diabetes"; these cases may perhaps be so labelled in the present state of our knowledge.

Physicians and surgeons who have reason to be interested in renal efficiency tests will obtain much useful information from a perusal of the chapters dealing with blood analysis of non-protein nitrogen, urea nitrogen, creatinine, uric acid, and chlorides, and also from the description of the phenolsulphonephthalein test, and the quantitative micro-methods of urine analysis. The importance of the determination of cholesterol in the blood is clearly recognised, and the author gives a simple, and apparently reliable, method for estimating this substance. The study of the variations in the cholesterol content of the blood is in its infancy, but bids fair to yield results of value.

To each chapter is appended a useful and fairly complete bibliography, and references are also given to various determinations of blood constituents which are of minor importance. The book is well printed, and contains a surprising amount of valuable information within small compass.

JOURNALS.

BRITISH JOURNAL OF SURGERY.—In the October issue, A. J. Walton discusses reconstruction of the common bile-duct in those cases where a cholecystenterostomy is unwise or impossible. He describes various groups of cases in which such a reconstruction is needed, and then reviews the usual operative procedures advised in the past. He gives the technique of an operation devised by him, first published in 1915, and a review of six cases in which he has used it.—Miss Maud Forrester-Brown examines a series of cases with a view to ascertaining the advantages and limitations of the many methods of bone grafting, more particularly in connexion with ununited fractures. In all she advocates a two-stage operation.—Sir D'Arcy Power's second eponym deals with the origin of "Baker's cysts" and "Baker's tracheotomy tubes."—D. P. Wilkie contributes an interesting article on Chronic Duodenal Ileus, the existence of which he has definitely established by a series of cases under his care. He goes on to describe the ætiology, pathology, symptoms, and treatment, and draws attention to the complications which may arise.—Zachary Cope describes five cases of appendicitis showing testicular signs.—E. E. Hughes records a case of spontaneous fracture of the humerus in an individual having obscure lesions in the right and left humerus, the right ischium, femur, tibia, and fibula. The lesions are not the same in all the affected bones, but some of them show unmistakable

Annotations.

"Ne quid nimis."

MEDICAL DEFENCE.

At the annual meeting of the Medical Defence Union, Ltd., held on Oct. 20th, at the rooms of the Medical Society of London, Sir Charles Ballance (President), in moving the adoption of the report for 1920-21, said that after his experience on the Council during the past 12 months he could not understand how any medical practitioner could fail to take advantage of the protection and security afforded by membership of the Union. Consideration of the report shows the Council to have good grounds for their claim that no diminution is to be found of the estimation in which the Union is held by the profession and by the general public. The total of membership reached a higher figure than in any previous year, and the Council is satisfied that the new arrangement whereby the premium for the Indemnity Insurance is included in the annual subscription (now raised to £1) payable by every member of the Union, is very generally appreciated. The single payment provides what is practically complete cover against all pecuniary risk, for, subject to certain conditions, each member of the Union is assured of indemnity against damages and costs to the extent of £2500 awarded against him in any case undertaken on his behalf by the Council of the Union. The report contains a reiteration of the warning previously given of the danger of placing the sale of a practice in the hands of more than one medical agency. In order to safeguard the interests of panel practitioners who employ assistants in their panel work, an addition has been drawn up for insertion in the restraining clause embodied in the ordinary agreement between principal and assistant; by this addition (1) the assistant undertakes to withdraw from the panel upon the termination of his assistancy, and (2) the principal is empowered to give notice on behalf of the assistant in the event of the assistant declining to do so. A form of restraining clause for the use of members has been drafted by the solicitor to the Union. No success attended the representations made to the Civil Service Commission by the Council with reference to the fee charged for the test examination—an examination invariably waived—of medical practitioners appointed on the staff of the Ministry of Health; but in every other direction the efforts of the Union on behalf of its members seem to have resulted in benefit to the latter. Disputed accounts, recovery of inquest fees and of moneys spent on vaccine for preventive inoculation of insured persons, difficulties with unsatisfactory locum-tenents, cases of forgery of practitioner's names—these and numerous other difficulties have been dealt with. The report points out that no medical practitioner enjoys immunity from attack, however skilfully and conscientiously he carries out his professional duties, and it is satisfactory to see the results of the Union's action in support of medical men who, failing that action, might have sustained more or less serious loss, either of reputation or of just material increment.

DIET IN RELATION TO NORMAL NUTRITION.

The principles underlying the subject of dietetics, with valuable illustrations upon the proper selection of foods, are clearly expounded in a recently issued report (No. 9, On Public Health and Medical Subjects), by Dr. J. M. Hamill, a medical officer of the Ministry of Health. They have been put together after numerous requests and are intended to give authoritative information to medical officers of health, medical practitioners, teachers, and lecturers. It is desirable that this information be widely disseminated, for much ill-health and physical impairment is due to dietetic deficiency from improper selection and use of foods. Many cases of vague ill-health may be caused by some inadequacy of the diet, and it is probable that numerous people are consuming a diet on the verge of inefficiency. The question of deciding what is sufficient and suitable food, or when a diet may be regarded as satisfactory, depends upon certain very definite principles. A large amount of physiological and biochemical research has been devoted during the last two or three decades to the elucidation and establishment of the essential factors. The different kinds of foodstuffs are not by any means of equal value, as is readily seen from the data of their chemical analyses; the food must contain adequate amounts of the so-called accessory food factors or vitamins, which at present cannot be expressed in concise terms. Food must firstly supply the energy needed for the maintenance of body temperature and for muscular work; the quantity so required depends upon the nature of the work, and varies from 2750 calories for sedentary work, such as that of a tailor, to 5500 calories for heavy work, such as that of a woodcutter, and higher quantities for still harder work. The figures are based on the requirements of a man of an average weight of 70 kilos. Body-weight is a variable, higher body-weight, of course, requiring a larger number of calories, while the lighter man requires relatively more calories per unit of body-weight. Weight for weight, woman requires less than a man, on the average one-fifth less. Children's requirements vary from 0·5 to 0·83 of that of a man, depending on their age, up to 14 years. Either of the proximate principles of the food (carbohydrate, fat or protein) can furnish this energy, but it is most adequately supplied by carbohydrate and fat, these two groups being, within limits, interchangeable. The function of protein is to replenish the wear and tear of tissues and to provide for growth. The most difficult problem is to decide the minimum quantity of protein required daily; the figure given by Atwater is 100 g. for light work, increasing to 125 g. for medium, and 150 g. for hard muscular work. For short periods less protein may suffice, even as little as 40 g. per day. In ordinary circumstances the analyses that have been made show that the usual consumption for light to medium work is from 80 to 100 g.; the lower amounts are fully adequate if the protein is largely of animal origin. The value of protein depends entirely upon the nature of the constituent amino-acids, many vegetable proteins being deficient in one or more of certain amino-acids which are absolutely necessary for life. The nutritional value of proteins of different sources has been compared and the results expressed under the term Biological Value of Proteins. Not only, therefore, must protein be sufficient in quantity but also of sufficient biological value; a diet containing protein of too low a biological value is now considered a probable cause of pellagra. A suitable mixture of inorganic salts is another important consideration in selecting a proper diet. The mineral requirements of the body are not so well known as the energy or protein requirements, but are satisfied by an ordinary well-mixed diet. The vitamin requirements are generally met by an ordinary well-mixed diet of natural foodstuffs. Disorders arising from vitamin deficiency can usually be traced to an ill-balanced diet or to a well-balanced one spoiled by commercial processes of manufacture or by improper cooking. The effect of commercial processes is best exemplified by the milling of cereals, which removes the B-vitamin. The suggestion that the loss of vitamin B of the grain may be compensated by baking with yeast has not been substantiated. The antiscorbutic or C-vitamin is present chiefly in fresh fruit and vegetables, and, again, these are variable. Oranges, lemons, cabbage, lettuce, &c., are richest in this vitamin. C-vitamin is a very unstable substance, the effect of ordinary drying processes being to destroy it; cooking has also a destructive action. The A-vitamin is contained in certain fats and green leaves. Butter is rich; lard poor; margarine varies according to its composition. All vitamins have their origin in vegetable food.

THE LANCET.

LONDON: SATURDAY, OCTOBER 29, 1921.

The Capitation Settlement.

On Thursday last agreement was reached between the Minister of Health and insurance practitioners in regard to the amount of the capitation fee to be paid to the practitioner on account of medical benefit under the Insurance Acts. The annual Conference of Representatives of Local Medical and Panel Committees held on this day—we summarise its proceedings on another page—reaffirmed its opinion that 13*s.* 6*d.* was the lowest capitation fee that should be offered for effective service, and that no justification existed for demanding any reduction below the arbitration award of 11*s.* in March, 1920. At the same time the Conference frankly recognised the force of the Minister's appeal to make some sacrifice for the common good in a great financial crisis, and after a deputation to the Minister from the Conference had ascertained that the state of the Exchequer did not admit at present of any higher fee than 9*s.* 6*d.*, the Conference agreed with unanimity and good humour to instruct its executive to accept the Minister's offer on grounds of citizenship. It was accepted on both sides that the question of the arbitration award was not reopened upon its own merits, but that, simply in view of the present admittedly desperate financial position of the country, panel doctors were prepared to bear their own share of sacrifice, provided that in so doing the public health did not suffer. That is, of course, the really crucial point. Speaking as chairman of the executive, Dr. Brackenbury is reported as having said to Sir Alfred Mond: "We do feel that there is a serious danger of the service becoming an unsatisfactory one"; a remark which has only been misunderstood in certain quarters because it has been taken apart from the speaker's assurance at the Conference that, whatever the capitation fee accepted, the panel doctor would render his best to his patient. It cannot be stated too forcibly that no question whatever arises of an insurance practitioner cutting his work to fit the reduced fee; but it is also abundantly clear that it is only a contented service which can produce results satisfactory to the panel patient. Fortunately, the Minister of Health, in regretting his inability to reconsider the fee of 9*s.* 6*d.*, was willing to guarantee its continuance for a period of two years, and in so doing eliminated, for a brief period at least, one disturbing element of uncertainty in the practitioner's daily life; at the same time he promised to see whether the reduction could be stated as rebate rather than depreciation of the basic fee.

Sir Alfred Mond, in the course of conversations, had already assured the panel executive that any sacrifice made by the medical profession now would not prejudice future discussion, for the Minister of Health has definitely promised that the whole subject of the administration of the Insurance Acts in regard to their effect on the health of the people shall fall under early review. This is the more likely to come about speedily, as both parties administering medical benefit express their desire for a wide and searching investigation, whereas by waiting until next spring a period of two complete years of medical benefit under the revised regulations will have elapsed. The official organ of the approved societies deprecates an inquiry at the present moment of extreme financial stringency. It may be recalled in passing that the total cost of medical benefit in England for the year 1920 approached £8,000,000, of which approximately £6,700,000 was paid to panel doctors. Other cash benefits under the Acts cost practically the same amount; sickness benefit, the principal of these, at its present enhanced rate of 15*s.* a week, is still actually less than the payment made to persons who are well but unemployed, and if only on this ground is likely to be increased rather than reduced. The cost of medical benefit is being met in the proportion of rather less than a half by the Exchequer and rather more than a half by the combined contributions of employers and employed, the ratio being roughly 19 to 22, and the reduction in the doctors' remuneration will be applied wholly in relief of Exchequer payments. With a working agreement reached on the subject of the capitation fee it becomes superfluous to consider how the sickness insurance principle would work out in this country in the absence of medical benefit, but it remains of interest to note the experience of Ireland where, from the first, this benefit was not granted.

INSURANCE WITHOUT MEDICAL BENEFIT.

The reasons why the medical benefit clauses in the National Health Insurance Acts did not apply to Ireland may be recalled with advantage. The Irish Poor-law system of medical attendance, which has now been in existence since the middle of the last century, provides medical treatment for every "poor person," whereas in England only a "destitute poor person" is entitled to attendance by the parish doctor. The term "poor person" has never been defined, as used in the Irish Poor-laws, and its vagueness has given rise to innumerable disputes, for it has permitted a large portion of the population to take advantage of rate-paid medical treatment without any proof of their right to such assistance. In other words, general practice as understood in England is almost unknown in rural Ireland. In the country districts not only all the wage-earning class, but also the small farmers have received habitually their medical attendance under the Poor-laws. Of course, while general practice, with its advantages, is largely absent, the club system has been also unable to flourish with all the abuses which centred round it before the passage of the National Insurance Act. There have been, of course, medical clubs in Dublin, Cork, Limerick, and some other of the larger towns, as well as in Belfast and a small industrial area in Armagh. Where clubs have existed abuses have not always been absent, and as a matter of fact it was the revolt of medical practitioners in Cork against the tyranny of club practice which started organised opposition against such abuses in England.

It was clear, therefore, that had the medical benefit of the Insurance Act been applied in Ireland, there would have been overlapping of two heterogeneous systems, one by which the whole population might enjoy rate-paid benefit by ranging itself under the undefined epithet of "poor," and one by which employers, employed, and the State provided medical treatment for a defined class. This is not the whole explanation of why the Bill was amended for Ireland as regards the medical benefit clauses before it became law; politics, of course, played their part. The Bill, which, as a whole, had roused the opposition gradually after the sixth month, leaving the child more susceptible during the first six years than at any other period of its life. The practical value of such a campaign, of course, depends upon two assumptions—viz: 1. That the Schick reaction is a reliable indicator of susceptibility to diphtheria. 2. That the injection of toxin-antitoxin actually confers active and lasting immunity. We pointed out some time ago that the crucial test of the value of the reaction had not been carried out, as no cases giving a negative reaction had been purposely infected with diphtheria. Whether toxin-antitoxin confers lasting immunity has yet to be demonstrated. So great, however, is the confidence in America that the methods proposed will stamp out diphtheria that public health authorities are beginning to hold parents responsible if their children contract the disease. This standpoint is strikingly illustrated by a letter sent by the sanitary authority in North Carolina to every home in which diphtheria occurred last year:—

> "Dear Friend,—We regret that you had a case of diphtheria in your home last year. We appreciate the care you took to keep this disease from spreading to others in your home or community. In the future you will be responsible if you have a case of diphtheria, as the North Carolina State Board of Health is preparing to furnish the doctors and the health officers toxin-antitoxin. When three doses of this are given, the person is protected against diphtheria for several years, possibly for life."

The importance of the issue is great and is worthy of earnest consideration and investigation on the part of those responsible for the maintenance of public health in this country.

GENERAL PARALYSIS IN OLD AGE.

Dr. Heinrich Herschmann,[1] assistant at the Psychiatric Department of the Vienna General Hospital, has made a clinical study of 84 cases of general paralysis which developed after the age of 60. Eighty of the patients were between 60 and 70 at the onset of the disease, and only four were over 70, the oldest being 75. Fifty-eight were males and 26, or about a third of the total, females. The relatively high proportion of women among aged general paralytics, a circumstance which had been previously observed by Kraepelin, Junius, and Arndt, is all the more remarkable as syphilitic infection after 50 is much rarer in women than in men. It is probable, therefore, that the interval between infection and the onset of general paralysis is longer in women than in men. The greater frequency of alcoholism in the male sex and the more intense strain on the nervous system caused by the struggle for existence probably account for the shortening of the incubation period. Of the 84 cases in the present series, 66 were kept under observation until their death, while the rest were sent home. The average duration of the illness of the 66 cases, reckoning from the time of their admission to the clinic, was 263 days, so that senile general paralysis does not assume a particularly rapid course. In only 22 of the 66 cases was death due to cachexia alone, the causes of death in the other cases being convulsive attacks, pneumonia, myocarditis, atheroma, or enteritis. The number of cases of tabo-paralysis was high, no less than 21, or exactly one quarter of all the cases, showing tabetic symptoms. In the 20 cases in which the date of syphilitic infection could be determined the length of the interval between it and the onset of general paralysis was remarkable; in six cases infection had occurred more than 40 years previously, in six more than 30 years, in seven more than 20 years, and in one 12 years before the onset of the psychosis. According to Dr. Herschmann, the special features of senile general paralysis are the rapid development of dementia, the loss of the power of orientation, nocturnal delirium, and, most of all, the frequency of the paranoid form. He suggests that this peculiar symptomatology is due to the histopathology of senile general paralysis, which will form the subject of a future communication.

RADIOLOGY AND PHYSIOTHERAPY.

IT was announced at the recent annual meeting of the British Association for the Advancement of Radiology and Physiotherapy that a certificate of incorporation had just been secured. Dr. Robert Knox, from the presidential chair, reviewed the work accomplished by the Association during the four years since its foundation, referring to the share taken in the institution of the Cambridge diploma in medical radiology and electrology. In conjunction with the Institution of Electrical Engineers, the Association had been successful in founding the Society of Radiographers, the Council of which was appointed in equal ratio by the B.A.R.P., the Institution, and the general body of its own members. The constitution of the Society of Radiographers had been approved by the General Medical Council, inasmuch as its diploma of membership (M.S.R.) was obtainable by examination only, all its members undertaking not to accept any patients for diagnosis or treatment except under the direction of a qualified medical man. In addition to its educational activities, Dr. Knox mentioned the policy recently initiated by the B.A.R.P. of issuing authoritative statements on medical subjects to the daily papers. The issue of manifestos approved by the Council but otherwise unsigned appeared to him to fulfil the joint requirement of being authoritative and at the same time free from any suggestion of personal bias. Dr. Knox expressed a hope to see in London some day a worthy institute of radiology, having its own museum and library, and perhaps its own clinic, and giving every possible facility for teaching and research.

THE UNSOLVED MYSTERIES OF ARTERITIS.

WHEN a pathologist with an international reputation publishes a series of cases closely observed by skilled clinicians during life, and searchingly investigated after death; and when his detailed summing-up ends in a frank avowal of ignorance, of inability to fix a truthfully descriptive label to the case, we are reminded that the sense of complete and nicely rounded-off knowledge is, most fortunately, withheld from every explorer. A few years ago our knowledge of the causes of arteritis was hardly even elementary, and when the relation of endarteritis to syphilis and of arteritis to tuberculosis had been noted, there was little more to be said—of importance, at any rate. Recent research has, indeed, added greatly to our appreciation of the part played by arteritis in such widely different diseases as CO poisoning, influenza, typhus and cerebro-spinal fever. That curious disease, periarteritis nodosa, is also better, though still imperfectly, understood. These recent advances should not, however, obscure the fact that we are still groping about the fringe of the problem, and this is the lesson on which Prof. F. Harbitz conscientiously insists when, in *Norsk Magazin for Lægevidenskaben* for September, 1921, he records one case after another of obscure arteritis observed at the Pathological-Anatomical Institute in Christiania. One of his cases was that of a man of 22 who was subject to idiopathic renal hæmorrhage. After it had continued off and on for about a year decapsulation was performed, and a piece of kidney excised for microscopic examination. This showed nothing abnormal, but as the hæmorrhage continued the whole kidney was removed. Its macroscopic appearance was normal, but the microscopic examination showed necrotic foci within which the arterioles were diseased; their walls were swollen, and the lumen of each vessel was reduced, in some places to the point of obliteration. The swelling of the walls was partly due to proliferation of the intima, partly to hyaline degeneration of the connective and elastic tissues. There was no sign of inflammation, syphilis, or arterio-sclerosis, and if the case was one of periarteritis nodosa, then this disease does occasionally develop as a strictly localised phenomenon. Arousing without satisfying curiosity, this case shows that the term idiopathic renal hæmorquestion can more fitly appeal to the consideration of a society whose fundamental idea is to correlate medical thought and endeavour with public work for general progress in health policy. We hope, therefore, that many persons of real experience along special lines as well as those who occupy public positions where knowledge of various sides of the question is necessary, will participate in the discussion; and we commend the subject to the consideration of other medical societies. A joint meeting of gynæcologists and neurologists might clear the ground of some of its rough places.

◆

Small-pox and Vaccination in U.S.A.

THERE is indisputable evidence that during recent years small-pox has been increasing in the United States, giving rise to some uneasiness in responsible quarters. Inquiry has of late been made into the matter by two experts whose report[1] was published in a recent issue of the U.S. Public Health Reports. Until quite recently the collection of health statistics in the United States was attended with difficulty and their accuracy was sometimes in doubt; but for the purposes of the above-named report it was found possible to obtain trustworthy official figures for the six years, 1915 to 1920, regarding the incidence of small-pox in 20 States, the combined population of which was estimated at 51 millions. At the same time evidence was obtained showing how the law as to vaccination, especially of school-children, was being enforced or neglected in each of these 20 States. A study of these collected facts and figures was then made, with a view of determining, as far as possible, the geographical distribution of the increased incidence of small-pox, and its relation with the vaccinal condition of the inhabitants as judged by the way in which the vaccination law in each State was enforced. The average rate of small-pox incidence in each State during the six years period was calculated by the formula $R = \frac{1000\ T}{6\,P - 15\,D}$, T representing the total number of officially reported cases for the period, P the 1920 population, D the annual increase (one-tenth of the intercensal difference), and R the rate of small-pox incidence per 1000 of the population. A list was then made of the 20 States in the order of their small-pox incidence-rate, the States showing the lowest rate coming first. The three States which had the lowest average small-pox rate were New York, with a rate of 0·026 per 1000, New Jersey 0·027, and Connecticut 0·09. The three States with the highest rates were Oregon with a rate of 1·48, Washington 1·72, and Kansas 2·0 per 1000 of the population. The 20 States were classified into four groups, according to their geographical position—namely, (1) Eastern, (2) Southern, (3) Pacific, and (4) Central. The average small-pox rate for the Eastern States was 0·04, for the Southern 0·58, for the Pacific 0·91, and for the Central States 1·14. The States of New York, New Jersey, and Connecticut, which had the lowest rates, are included in the Eastern group. Oregon and Washington, which were among the highest rates, are in the Pacific group, and Kansas, which had the highest rate of all, is in the Central group of States.

There is no general vaccination law for the whole of the United States, but vaccination of children is generally secured by making it a condition of admission to school. Each State makes its own enactments as to vaccination, but in some States, although the law exists, it is not enforced. Vaccination of school-children appears to be well carried out in the Eastern States, particularly in the State of New York, where vaccination is a condition of school attendance in cities of the first and second classes, in which it is estimated that 100 per cent. of school-children are vaccinated. Outside the larger cities the enforcement of vaccination is less satisfactory. In the State of New Jersey the law directs that boards of education may prohibit the attendance of any unvaccinated child at school. This condition is strictly enforced in the large cities. In this State vaccination campaigns at previous times of epidemic small-pox have, in some instances, resulted in the protection of about 80 per cent. of the community. The attitude of the citizens of the Eastern States to vaccination is on the whole favourable. On the other hand, in the Pacific and Central States this attitude is less satisfactory. The exclusion of unvaccinated children from school, although enacted by law, is frequently not enforced. In the State of Washington the law has been neglected for some years, and in 1919 it was finally repealed altogether. Kansas, with the highest incidence-rate among the 20 States, does not enforce vaccination, and even in some of what are termed "progressive districts," approximately 80 per cent. of the school-children are unvaccinated. From consideration of the above and other facts and figures, it appears to the authors of the report that small-pox prevalence "depends upon the popular vote." In those States where popular sentiment backs up the enforcement of vaccination, small-pox is practically negligible. Where, however, the law gives discretionary powers to local authorities, or to individuals, as regards enforcement of vaccination, the small-pox incidence-rate tends to rise; and where there is absence of compulsory powers, or in States where there is no vaccination law at all, small-pox reaches a high average rate of incidence.

The type of small-pox now prevalent in the United States is, as our readers are aware, comparatively mild. But there is no assurance that this type will continue. There is always a possibility of the introduction of a more virulent strain of the infection into the States from Mexico or South America, where small-pox is continually occurring. The fact that nearly 58,000 small-pox cases were reported during 1920, in the 20 States under consideration, containing only about half the population of the United States, is a sufficient proof that the disease is widespread and likely before long to become severely epidemic in the absence of general vaccination. In view of the large amount of available evidence it is useless to deny nowadays the favourable influence which vaccination exerts in the protection of communities and individuals against small-pox. But, as in the past, it will need a severe shock in the form of a serious and fatal epidemic to rouse the public, not only in the United States but in England as well, from the sense of false security into which it has fallen as regards small-pox and the prophylactic value of vaccination and revaccination.

UNIVERSITY OF LEEDS.—Sir Edward Brotherton's gift for the endowment of bacteriological work at the University, to which we have already referred, was officially reported to the University Council on Oct. 10th. A resolution of appreciation was passed and the Council announced their intention of founding a chair of bacteriology, to which will be attached in perpetuity the donor's name.

[1] Small-pox in Twenty States, 1915 to 1920. By John N. Force, Special Expert; and James P. Leake, Surgeon, U.S. Public Health Service. Public Health Reports for August 19th, 1921.

side of the third or transitional year, the students are engaged on this for about one-half of each week. During the hours they spend in the hospitals they are under the immediate supervision of a member of the staff, and either in the casualty rooms or wards or elsewhere they are systematically instructed in the elementary essentials of clinical work. As far as possible the subjects demonstrated clinically are made to correspond with the subjects which are being dealt with during the remainder of the week in the laboratory. No novelty is claimed for the scheme. On the contrary, it is a reversion to the practice of many medical schools a generation ago, as students of those days will remember. Those, however, who remember having to do six months' hospital practice before entering for their examinations in anatomy and physiology will remember also that the hospital practice was then a somewhat perfunctory affair. It was often regarded as an interference with the earlier studies. The student had to get "signed up" for it, and to this extent only it was important, but little or no attempt was made to show that clinical practice had any bearing on the earlier subjects. The present experiment, which has its counterpart elsewhere, will be watched with interest by all those responsible for training students of medicine.

THE ROYAL SOCIETY OF MEDICINE: SOCIAL EVENINGS.

The Council of the Royal Society of Medicine has decided to resume the Social Evenings, having regard to the general appreciation by the Fellows of the opportunities offered at such gatherings for scientific and social inter-communication. The first meeting has been fixed for Monday, Oct. 31st, when the Fellows and their friends will be received by the President of the Society, Sir John Bland-Sutton, with Lady Bland-Sutton, at 8.30 P.M., after which the President will deliver a short address on "Choroid Plexuses and Psammomas." Those who may recall an address delivered by Sir John Bland-Sutton, at a previous similar gathering, upon "Gizzards and Counterfeit Gizzards," will attend the Social Evening with pleasurable anticipation. The library of the Society will be open to the guests and various objects of interest will be on exhibition, while the lighter side of the reception will be represented by music, refreshments, and smoking. Fellows may invite guests, and tickets are not required.

In view of the large number of protests received from local authorities in regard to the threatened reduction from 50 to 5 per cent. in the Treasury grant towards the supply of milk to mothers and young children, the more generous scale has been extended by the Ministry of Health until March 31st, 1922.

The St. Pancras Borough Council has unfortunately maintained its attitude with regard to the dismissal of Dr. Gladys Miall-Smith. By this act a competent officer loses work for which she was not only well fitted but was actually discharging in a satisfactory manner. A question will be put to the Minister of Health on the subject.

At the Royal College of Physicians of London on Nov. 1st Dr. F. Parkes Weber will deliver the Mitchell Lecture on the Relations of Tuberculosis to General Conditions of the Body and Diseases other than Tuberculosis; on Nov. 3rd Dr. Michael Grabham will deliver the Bradshaw Lecture on Sub-tropical Esculents; and on Nov. 8th and 10th Dr. R. O. Moon will deliver the FitzPatrick Lectures on Hippocrates in Relation to the Philosophy of his Time. The hour in each case is 5 P.M.

The Services.

THE MINISTRY OF PENSIONS: CONCURRENT TREATMENT AND TRAINING.

The rules governing the admission of disabled ex-officers and nurses to concurrent treatment and training have been revised in the light of recently published decisions of the Ministry of Labour, and it must be remembered that the concurrent treatment and training are normally preliminary to passage under that department. Applications for concurrent treatment and training must reach the Commissioners of Medical Services of the various regions not later than the end of this month. Such applications cannot be entertained later unless the applicant has been demobilised or discharged for more than a year, or can show that, though out of the Services for a longer period, there has been continuous treatment, additional or retired pay or pension, or that unsuccessful endeavour since discharge has been made to resume pre-war occupation or to enter one equally remunerative. These arrangements do not at present apply to tuberculous cases.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. C. L. W. Bunton is placed on the retd. list at own request.

ROYAL ARMY MEDICAL CORPS.

Maj. A. C. H. Gray relinquishes the temp. rank of Lt.-Col.

Capt. L. Buckley retires, receiving a gratuity.

Officers relinquishing their commns.:—Temp. Maj. C. J. Marsh, and retains the rank of Maj. Temp. Capts. retaining the rank of Capt.: G. L. Lawlor, H. H. R. Bayley, I. A. Davidson, H. Gibson, H. E. M. Baylis, C. L. Herklots, and W. St. A. Hubbard.

ARMY DENTAL CORPS.

Temp. Capt. B. E. Gentleman, Dental Surg., from Spec. List, to be Lt., and to be temp. Capt.

Temp. Capt. W. Meeke relinquishes his commn. on ceasing to be empld. as a Dental Surg., and retains the rank of Capt.

SPECIAL RESERVE OF OFFICERS.

Capt. K. N. G. Bailey relinquishes his commn. and retains the rank of Capt.

TERRITORIAL ARMY.

Capt. G. F. Shepherd (late R.A.M.C.) to be Lt., and relinquishes the rank of Capt.

INDIA AND THE INDIAN MEDICAL SERVICE.

The King has approved the retirement of Maj.-Gen. P. Carr-White, and the resignation of Capt. G. B. Harland.

Maj. R. H. Lee has been appointed to hold visiting charge of the office of Agency Surgeon, Eastern Rajputana States. Majs. H. W. Pierpoint, D. Heron, J. Husband, and A. N. Dickson have been confirmed in their appointment as Agency Surgeons. Lt.-Col. W. D. H. Stevenson, Assistant Director-General, has proceeded on a year's leave, and Maj. J. A. Cruickshank, of the Bacteriological Department, has been posted to Madras and appointed Assistant Director, King Institute, Guindy.

DEATHS IN THE SERVICES.

Surg.-Gen. Sir William Deane Wilson, K.C.M.G., R.A.M.C., who died at his residence at Westfield in Sussex on Oct. 19th, aged 77, saw service in the Afghan War of 1878–80, and in the Egyptian Campaign of 1882–84, being mentioned in despatches and receiving medals and clasps on both occasions. In 1898 he was Principal Medical Officer for the Western District at Devonport, and was created K.C.M.G. in 1900.

News has reached this country of the conditions under which Lt.-Col. E. A. Roberts, D.S.O., Third Surgeon of the General Hospital, Madras, was drowned on the Madras beach last month. The deceased went with a friend to bathe, and going out of his depth called for help. The friend reached him with great difficulty, and succeeded in bringing him to shore, where he rendered all possible aid, but without avail. An inquest was held, and the jury returned a verdict that death was due to accident.

Donations and Bequests.—The late Mr. Wm. Mitchell, sometime millwright at Stuartfield, and latterly residing at Hawthorn Cottage, Station-road, Mintlaw, has left, free of legacy duty, £100 to the Aberdeen Royal Infirmary, and £100 to the Aberdeen Sick Children's Hospital.—The Chelsea Hospital for Women has received a grant of £150 from the Alexandra Day Fund.

Milk fat will be deficient in A-vitamin if the animal be not fed upon food containing it, such as green leaf, which is its ultimate source. The antiscorbutic value of milk depends upon the animal's food. The two best foods are milk and green leaves. Milk supplies good protein and mineral matter, and vitamins if from properly fed animals. Green leaves are said to contain good protein, and they are certainly rich in vitamins. An ill-balanced diet will therefore be made adequate by the inclusion of milk and green vegetables.

THE SOLDIER'S LOAD.

WHAT weight can a soldier carry and yet march and fight well? Major N. V. Lothian deals with this important question in the opening paper of the *Journal of the Royal Army Medical Corps* for October. The diseases ascribed to overloading have been pulmonary emphysema, so-called soldier's heart, and, tentatively, trench nephritis. Some burden the soldier must have: arms, armour, spade, clothing, food, to which he adds souvenirs; together these cannot weigh less than 40 lb., and men have carried 88. The problem has faced soldiers of all times. The Athenian hoplite in battle carried 80 lb., but each had an attendant to carry his equipment to the field. Thus heavily weighted they were little mobile, consequently no sooner were they, as we may put it, standardised, than light infantry in considerable numbers were added to all armies, and it was these who gave Philip of Macedon much of his success. If a soldier is well trained he can carry greater weights more easily, so the Romans specially trained their recruits to carry a load of 45 lb., while the legionaries each month did three 20-mile route marches in heavy marching order, carrying about 50 lb. His pack he carried on a forked stick, introduced into the service by Marius, and called after him, "Marius's mule," but much of his burden was, on service, borne for him by a servant (calo) or in carts, as may be seen on the column of Trajan and elsewhere. Major Lothian's paper is a valuable contribution to military science, worthy of the Army School of Hygiene from which it comes, though it is defaced by careless printing of Latin words.

IRRADIATION OF LYMPHOID TISSUE.

As a result of clinical and experimental investigations into the action of radium and X rays upon normal and diseased lymphoid tissue carried out in the Department of Cancer Research of the Montefiore Hospital, New York, Dr. Isaac Levin[1] concludes that the lymphocytes in the blood stream and lymphoid tissue generally throughout the body are extremely sensitive to these radiations. Dr. Levin is not alone in this opinion; reports issued from various centres of radium-therapy will generally be found to include data showing the remarkable susceptibility of diseased lymphoid tissue to radium. Lympho-sarcomata figure among the tumours giving the highest percentage of favourable clinical results. Dr. Levin's paper consists for the most part of short descriptions of clinical cases illustrating his conclusions. Apart from the immediate clinical results, his observations are valuable as factors which must be taken into account when any sort of generalisation is attempted on this subject. More recent studies have shown that the physiological response of the organism must in no case be ignored when generalised exposures to radiation are given. Levin states that the rays do not act merely as a local agent, but produce a generalised effect on the lymphoid system of the whole organism. The evidence for this statement is based upon observations such as the following. In a case of lymphosarcoma, examination showed a large diffuse mass occupying the whole of the right axilla and invading the pectoral muscles. In the left axilla was an enlarged freely movable gland, the size of a hen's egg. The radium applications were made only at the right axilla, with complete disappearance of the mass there, as well as that in the other axilla; this and other cases cited by the author are probably paralleled by the experiences of radiologists elsewhere. Dr. Levin comments upon the hypothesis that specific enzymes are freed from the disintegrating lymphocytes, but offers the timely reminder that hardly any work has yet been done to clear up the problem. As the field of utility of these radiations widens in medicine, the necessity for investigations becomes increasingly urgent, for the feeling of insecurity of any practice based upon empiricism increases with the dimensions of the superstructure.

THE EFFECTS OF PROLONGED DEPRIVATION OF SLEEP.

Prof. G. W. Crile,[1] in his recent studies on exhaustion, has extended his observations on this subject, and has determined the effects in rabbits of prolonged deprivation of sleep—96–118 hours. Marked changes are thereby produced in the cells of Purkinje in the cerebellum; in the first stage there is an increase of the chromatin material—both in its diffuse and particulate form, in the plasma and size of the nucleus; the cells contain an average amount of chromatin, but changes manifest themselves in the dendrites. Then the chromatin diminishes, and its remains collect around the periphery of the cell and nucleus. In the next stage the chromatin completely disappears, the cytoplasm showing disintegrative changes, and vacuolisation; somewhat similar changes affect the nucleus, and in extreme cases there seems to be death and complete disintegration of the cells. It is suggested that neither man nor animal can survive the loss of 15 per cent. of the brain cells. In eight experiments, six animals showed more or less pronounced changes in the liver, especially at the periphery of the lobules. The nuclei lay excentrically and were deformed, the granules diminished or absent, vacuoles were present and the cell as a whole materially changed, including the disappearance of its glycogen. In five cases out of six the medulla of the adrenal glands was not affected, while the cortex in six out of eight cases showed changes and disintegration after loss of the nuclei. No marked changes were noted in the thyroid, pancreas, kidneys, spleen, stomach, or intestines. By inducing sleep at the end of a sleepless period, and by the action of different agents, the author endeavoured to mitigate the effects and restore the activities of the injured cells. Sleep and nitrous oxide have a marked recuperative effect, except in cases where the disintegration of the brain cells has proceeded too far. As experimental poisoning by acids produces similar changes in the cells of the brain, liver and kidney, the pH of the blood was determined, but it was found that sleeplessness produced no marked change, the pH being nearly the same during the sleeping as in the waking condition.

THE PREVENTION OF DIPHTHERIA.

LAST winter the incidence of diphtheria was high, the mortality correspondingly high, and the number of cases notified so far this autumn points to a severe winter epidemic. In America the mortality from diphtheria is apparently heavier than it is in England, and the public health authorities there are instituting a campaign to stamp out the disease on the principle that since its prevention and cure are known, the disease should be eradicable. The method of the campaign is to confer active immunity on all children between the ages of 6 months and 6 years by the injection of three doses of toxin-antitoxin, thereby rendering the children insusceptible of infection for several years or maybe for life. This is especially applicable to young children, as the mortality from diphtheria as well as the incidence of the disease is vastly greater in the younger age periods. Children at birth are found by means of the Schick reaction to have a natural immunity to diphtheria, which fades away

Disciplinary Procedure.

The I.A.C. was authorised to press for the play of public opinion on the disciplinary procedure in alleged breaches of agreement by a panel practitioner. In cases of removal from the panel the inquiry was in practice a public inquiry, though there was no provision that it must be public. In most cases, however, involving the infliction of a fine on the practitioner by withholding the Treasury grant, the inquiry was conducted in private by one or more officers of the Ministry without prescribed rules of procedure. If the practitioner desired to make oral representations he must do so in person, though in practice he was allowed to be accompanied by a representative of a medical defence society or by a solicitor. Cases had occurred in which it seemed to panel or to insurance committees that the fine inflicted has been disproportionate to the neglect or offence which occasioned it. The I.A.C. therefore thought it desirable for the sake of everyone concerned that public opinion should in some way have an opportunity of being informed and satisfied in these cases. The Conference took this view and authorised the I.A.C. to enter into negotiations with the Ministry, so that representatives of panel committees or other recognised professional bodies might be present at the inquiry, or so that the facts of the case as known to the Ministry and the fine proposed to be inflicted, should be submitted to the panel committee for its observations before the penalty became operative.

Inflated Index Registers.

The I.A.C. was instructed to bring before the Ministry the lax and dilatory manner in which some approved societies carried out the requirements of the Ministry in respect of such of their members as had ceased to be insured. A delegate gave as an instance the fact that he still had on his list the name of a boy who died in 1915.

Coöperation with Unqualified Practitioners.

Herefordshire asked the I.A.C. to take such action as would relieve panel practitioners of their obligation to supply certificates and treatment to insured persons who were being treated by bone-setters or other unqualified practitioners. It was pointed out that no such obligation in fact existed and that the practitioner was advised to cease attendance and make immediate application for the removal of the name from his list. The full support of the B.M.A. was offered to any practitioner who was obliged to fight such a case on behalf of the medical profession.

Regional Medical Officers.

A motion to abolish the office of regional medical officer in the interests of economy was ruled out of order by the chairman, who pointed out that the I.A.C. approved of the appointment of these officers and had indeed been partly responsible for the initiation of the policy.

Superannuation.

The last motion to be taken was by London to the effect that provision for the superannuation of practitioners working under the National Insurance Acts should be included in the terms of service, and that in any negotiation as to remuneration such provision should be taken into account. Dr. Cardale reminded the Conference that a practicable scheme was submitted two years ago and that its small initial cost would be likely to weigh with the Ministry of Health if asked to consider it. The chairman suggested that a matter of such importance could not be adequately dealt with at so late an hour, and it was left to the London representative to bring the matter before the I.A.C.

After passing by acclamation votes of thanks to Dr. Dain, chairman of the Conference, and Dr. Brackenbury, chairman of the Insurance Acts Committee, the Conference rose at 10.30 P.M.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

International Congress of Ophthalmologists at Vienna.

THE Ophthalmological Society of Vienna recently arranged an international congress in honour of the veteran Prof. Ernst Fuchs, inviting the attendance of all members of ophthalmological societies throughout the world. The significance of the meeting lay in the fact that it was the first really international scientific congress held since the outbreak of war. Not only neutral countries, but also former enemies—the U.S.A., Japan, Latin America, and Italy—were represented by their leading oculists. Only Great Britain, France, and Belgium sent no delegates. The meetings were held from August 3rd to 6th; 43 papers were read, and 20 demonstrations given in the eye clinics of the University of Vienna. The high standard of the work submitted was made evident by the large attendance of delegates at every session. Adherents of the old classic ophthalmology and investigators of more modern tendencies were equally energetic in pressing their claims to attention. The transactions were preceded by an address by Prof. Fuchs; and the hundredth anniversary of the birth of Helmholtz was the occasion of an eloquent speech by Prof. Friedrich Dimmer. Prof. M. Marquez de Rodriguez (Spain), D. Gourfein (Switzerland), and others; Maggiore (Italy) and Hagen (Norway) also took part in the opening ceremony. Amongst the interesting contributions to the congress may be mentioned a paper on glaucoma, presented by several German ophthalmologists, in which it was shown that Graefe's classic method of iridectomy still held its own as the best means of combating this condition. Nevertheless, modern research had shown that whilst treatment with instillations of pilocarpine alone had little effect, marked improvement resulted when pilocarpine was combined with the internal use of thyroid extract. Dr. Ernst Hertel (Leipsic) reported excellent results from this treatment. Suction seems of late years to have assumed importance. Prof. J. A. Barraquer y Roviralta (Barcelona) has applied it for extraction of cataracts by means of a small suction-pump driven by electricity; Dr. Zur Nedden (Dusseldorf) has used the same means to remove the corpus vitreum in cases of fresh infected injuries and of hæmorrhage of corpus vitreum and retina, or acute inflammations. A modification of the old methods of removing iron particles from the bulbus by means of a magnet was demonstrated by Dr. Gilbert (Munich), who, by the introduction of a very strong magnet into the interior of the bulbus, has removed particles even from the retinal layers. Experimental syphilis of the eye of rabbits was described by Dr. Iggersheim (Göttingen), who contended that the posterior strata of the cornea and the fibrinous deposits on the posterior aspect of the cornea harbour nearly all the spirochætes living in the eye. Accordingly he injected a new soluble preparation of salvarsan into the anterior chamber of the eye, with excellent results. Amongst other papers of interest was that by Drs. Koppanyi and Kolmer on the transplantation of the eyes of rats. These two authors claimed to have obtained successful function in transplanted eyes. The experiments were conducted in the Biological Department of the Academy of Science at Vienna, and the conclusions were received with reserve, but caused sensation. A paper on X ray treatment of tumours of the hypophysis was presented by Prof. Müller (Vienna) and Dr. Czepa, who had obtained good results without recourse to operation. Other cases where the hypophysis was attacked through the nasal route (method of Hirsch), were afterwards subjected to radium treatment, with equally satisfactory effect. In all cases the most welcome effect was the cessation of the characteristic violent headaches after one application. Acromegalic symptoms also yielded readily to this treatment. Of course, not all cases rhage is apt to be misapplied, the hæmorrhage being due to organic disease of the kidney. In addition to another case of inflammation of the arteries and veins of the skin associated with purpura rheumatica, Prof. Harbitz records two cases of arteritis of the brain. He concludes that true arteritis is much more common than was formerly supposed to be the case, that its causes are very varied, and that the task of distinguishing between the yet unknown forms of arteritis and those of syphilis, periarteritis nodosa, and even of tuberculosis may be extraordinarily difficult.

HEMIHYPERTROPHY AND MENTAL DEFECT.

Dr. Arnold Gesell,[1] of New Haven, Connecticut, who reports an example of hemihypertrophy associated with mental defect, describes hemihypertrophy as one of the rarest of developmental anomalies. He has collected 40 cases of true hemihypertrophy or total unilateral hypertrophy, including one under his own care, and 30 examples of partial and crossed hypertrophy which is much more common. Of the 40 cases only 5 were adults, 19 were males, 17 females, and in 4 the sex was not specified. In 27, or almost 70 per cent., the hemihypertrophy was on the right side. In 15 cases it was definitely stated that all the tissues were involved in the hypertrophy, in 19 cases abnormalities of the skin were mentioned as a complication, in 3 the skin was reported as normal, and in the remainder no details were given. As regards the mental condition, in 29 cases no information was supplied, in many instances the subject being too young for mental examination, in 6 cases the mentality was reported as normal, and in 5 cases, or 13 per cent., it was reported as defective. According to Dr. Gesell, who maintains that hemihypertrophy is not a hereditary character but a morphological anomaly dating back to an early embryonic stage, hemihypertrophy may be interpreted as an atypical or imperfect form of twinning, a variant of the same process which may produce a double-headed monster or a perfectly ordinary normal individual, the latter being an organism in whom there has been a precisely balanced inhibition of the biological process of bilateral doubling. The complication of mental defect is attributed to an abnormality in the process of bilateral twinning which involves a disturbance of normal tissue development.

INTERNATIONAL ASSOCIATION OF HISTORY OF MEDICINE.

A MEETING to form an International Association of the History of Medicine was held in Paris on Oct. 8th, at the Faculty of Medicine, at which representatives from Great Britain, Holland, Belgium, Spain, Portugal, Denmark, Norway, Switzerland, Roumania, France, and other countries were present. The object of this Association is to pursue the study of the history of medicine by means of research, bibliography, and communications presented by its members for discussion at the future meetings of the International Congress. The Association is the outcome of the successful International Congresses, the first of which was held in Antwerp in 1920, and the second in July last in Paris. It was then decided to form a permanent bureau or committee to meet in Paris to draw up a constitution and make regulations to indicate to members various subjects for research and investigation, so as to ensure unity and continuity, and to make their work of practical value. Prof. Jeanselme (Paris) presided and extended a cordial greeting to the foreign representatives. Prof. Laignel-Lavastine, General Secretary of the Faculty of Medicine of Paris, then outlined the proposed constitution. He suggested that the Permanent Committee should consist of a president, vice-presidents, secretary and treasurer, and delegates from each country represented. This proposition was accepted by the meeting, and Dr. Tricot-Royer (Antwerp) was elected president, Dr. C. Singer (Great Britain), Profs. Giordano (Italy), Ménétrier, and Jeanselme (France) were appointed vice-presidents, Dr. Fosseyeux archivist and secretary, and Dr. Boulanger treasurer, of the Permanent Committee of the Bureau.

Dr. Singer conveyed an invitation from the Section of the History of Medicine of the Royal Society of Medicine for the third International Congress to meet in London next year, which was cordially accepted, and the approximate date was fixed for the meeting for July 24th to 29th, 1922. The following subjects were suggested for the consideration of the members at the next Congress: (1) Principal seats of endemic and epidemic diseases in the Classical Orient during the Middle Ages. (2) History of Anatomy. (3) Revival of medical knowledge during the sixteenth century. The draft by-laws of the Association will be submitted to the Permanent Committee of the Bureau at the next meeting, which it is expected will be held in December next.

THE CAMBRIDGE CHAIR OF ANATOMY.

IN an annotation of Oct. 15th upon the innervation of striped muscle we alluded to Dr. J. T. Wilson as Challis Professor of Anatomy in the University of Sydney. This was an error of forgetfulness, for Prof. Wilson has now succeeded the late Prof. Alexander Macalister as professor of anatomy in the University of Cambridge, and began his work there this term. Prof. Wilson's translation from Sydney to Cambridge was due to the fact that the electors considered him the most likely man possible to build up a research anatomical department in the University of Cambridge. During his stay at Sydney he has educated a long line of sound anatomists, notable among these being Prof. Elliot Smith, while he is himself a pupil of that famous teacher of anatomists, Sir William Turner. Under Prof. Wilson the chair of anatomy at Cambridge should bring forth great things.

UNIVERSITY OF SHEFFIELD: UNION OF MEDICAL SCHOOL AND HOSPITAL.

THIS term new regulations come into force whereby an attempt is being made by the University of Sheffield to bring into closer contact the laboratory studies of anatomy and physiology, on the one hand, and the elementary principles of medicine and surgery on the other, and to show the student, whilst still engaged in the former studies, their practical application to the latter. It is hoped to attain this object by making the third or middle year of the curriculum into a kind of dove-tailed joint between laboratory and hospital. In order to bring this about the second M.B. examination in general anatomy and physiology has to be taken at the end of the second year—that is to say, six months earlier than heretofore; whilst a further examination in these subjects, with the addition of pathology and pharmacology, is held in the third M.B. examination at the close of the fourth year. Under this plan it is obviously impossible for the second M.B. examination to cover the whole of the subjects in detail, since the students will have studied them for one year only. The difficulty of the scheme lies in the proper distribution of the teaching of the subjects before and after the second M.B., and the grading of the examinations. At present the scheme is in the experimental stage. The second M.B. examination held last June was the first to be held at an earlier stage in the curriculum, and the results were distinctly encouraging. Possibly the anxiety of the teachers to show good results, and certainly the keenness of the students to make the scheme a success, played some part here. Even those who were inclined to doubt the wisdom of the innovation admitted that the outcome was better than anticipated. As regards the clinical

Public Health Services.

SCARLET FEVER AND DIPHTHERIA IN LONDON.

REPLYING last week to a question in the London County Council, the chairman of the Public Health Committee stated that the number of cases of scarlet fever notified in London had recently increased, as was usually the case at this time of the year. The cases notified in the first and second weeks of October were 1155 and 1136 respectively. The disease was of a mild type. In the case of diphtheria, the corresponding figures were 389 and 417. The usual autumnal increase generally ceased later than in the case of scarlet fever and it was not surprising that the notifications were still increasing. Sufficient accommodation had been found for London cases by using beds earmarked for other infectious diseases not at present prevalent. Captain Warburg added that, notwithstanding the high prevalence of diphtheria and scarlet fever, and the resulting increase in deaths from these causes, the deaths from all causes during the first three-quarters of this year showed a mortality below anything hitherto recorded in London.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

CHESTERFIELD RURAL DISTRICT.

THE estimated population for 1920 was 74,148. Dr. Herbert Peck states that at the last census 55 per cent. of the occupied males were employed in coal-mining and quarrying, 11 per cent. in iron and allied trades, and 8 per cent. in agriculture. The birth-rate in 1920 was 32·47, and in the previous quinquennium 25·8. The death-rate during 1920 was 12·08 and the infant mortality rate 92·6, which latter, Dr. Peck remarks, cannot be considered satisfactory. The death-rate from tuberculosis was comparatively low, as one is accustomed to expect in a coal-mining district—viz., 0·63 in 1920 and 0·98 during the previous 10 years. Dr. Peck says: "The conversion of privies to water-closets is the greatest sanitary need of the district," but further reservoirs are needed before the conversion of the privies can be undertaken on the scale required. Dr. Peck expects the infant mortality rate to remain high until the abolition of the privy-midden system. He also thinks that some better system of disposal of refuse than tipping should be found. Successful vaccinations, which in 1907 numbered 58·9 per cent. of the births, have decreased year by year, and in 1920 they only numbered 12·9 per cent. of the births. There are 11 health visitors and 11 welfare centres, but, Dr. Peck believes, the poorer mothers, who would benefit most by bringing their babies to the centres, keep away on account of inability to provide good clothing for their babies and themselves. Out of 11 notified cases of ophthalmia neonatorum two of the infants were left partly blind; one was still under treatment; the remainder completely recovered. "The shortage of houses was estimated by the Minister of Health at 1619 at the end of 1919."

HULL.

Dr. J. Wright Mason tells us that the birth-rate, 29·1, and the death-rate, 13·2, are calculated on a population of 290,808. Other important statistics for 1920 were: infant mortality rate, 98; death-rate from pulmonary tuberculosis, 0·80; and from other tuberculous diseases, 0·34. Dr. Mason says that with the exception of diarrhœa, the mortality from infectious diseases was somewhat low. We note that for diarrhœa and enteritis under 2 years per 1000 births, Hull had the highest death-rate among the 20 large towns. There is a very complete maternity and child welfare scheme, including a maternity home, in which 236 confinements took place in 1920. The corporation have decided not to take over the two creches which are still at work in Hull. A third creche was closed during the year.

Dr. James A. Raeburn, the tuberculosis officer, gives particulars as to the work of the dispensary and allied institutions. He mentions that a large proportion of tuberculous patients give "dock labourer" as their occupation, and attributes this to the irregular work and pay, and to the fact that the less skilled and educated, who are not particular about their housing accommodation, drift into this work. Dr. Raeburn also thinks that unhealthy living conditions below deck account for the fact that so many sea-faring men and fishermen on trawlers become tuberculous. These speculations would be more interesting if it were possible to obtain the data from which to calculate the death-rate for these occupations. We should also like to see an analysis of the Hull tuberculosis rate for males, females, and children, as, judging from the nature of the men's occupations, the male phthisis rate in Hull ought to be lower than in most towns. The V.D. report shows that there were 1336 new patients suffering from venereal diseases, and that during the year 619 patients gave up attendance before completing a course of treatment or before a final test as to cure. Attendance is, of course, more likely to be interrupted in a seaport clinic than in an inland one. Dr. Mason has had the card advertising free treatment at the clinic translated into eight languages for the benefit of the foreign seamen coming to the port. 371 observations were taken of chimneys for black smoke, but "in no case has it been necessary to serve a statutory notice." We hope that the non-service of notices was due to the prompt action of the owners of chimneys rather than to the leniency of the local authority, but we should like some details as to what is considered an excessive emission of black smoke in Hull. We note that there are 37,966 water-closets and 41,316 privies in Hull, and that a privy conversion scheme is in hand. Last year 58 conversions took place. At this rate of progress the scheme will last long.

HERTFORDSHIRE.

Dr. H. Hyslop Thomson mentions with satisfaction that the death-rate for the county, which was 11·38 in 1919, has fallen to 9·92 in 1920, while the birth-rate has gone up from 14·69 to 22·3. The infant mortality rate was 49·5 in 1919 and 48·46 in 1920. There have been slight falls in the death-rates from pulmonary tuberculosis and epidemic diarrhœa, but a further increase in the death-rate from cancer. The Registrar-General estimates the population at 325,962 for birth-rate and at 325,684 for death-rate. The general death-rate was 9·66 in the urban districts, and 10·55 in the rural districts, while the infant mortality rate was 49·39 in the urban districts compared with 46·35 in the rural. Dr. Thomson complains that there are three large dumps for London refuse in the county. He says: "It is remarkable that one public health authority should have power to deposit such large quantities of refuse on ground within the jurisdiction of another public health authority without its knowledge or approval, or without being subjected to certain conditions," and asks: "Is it a mere coincidence that during 1920 the highest death-rate from infantile diarrhœa in the rural districts was in the district where two large refuse dumps are situated?" For V.D. purposes Hertfordshire is included in the London treatment scheme. During the year Kingsmead School was opened as a special school for mentally defective children, and has already proved its value. To quote Dr. Thomson: "Success, however, depends on the grade of defect and the age at which the child is admitted to the school. If taken early many of these defective children will become good manual workers in the future."

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The Entrance Scholarship in Anatomy and Physiology has been divided equally between C. E. Newman, B.A., of Magdalene College, Cambridge, and P. B. Wilkinson, of King's College, London.

THE PANEL CONFERENCE.

THE annual conference of representatives of local medical and panel committees was held in London on Thursday, Oct. 20th, and transacted its business in the course of a single strenuous day. Dr. H. G. Dain, of Birmingham, occupied the chair, being supported by Dr. H. B. Brackenbury (chairman) and other members of the Insurance Acts Committee (hereafter briefly called I.A.C.).

An Independent Executive.

After formal business a motion by Kent was taken urging that the views of panel committees should be focussed by a central statutory committee elected solely by panel committees. This gave the Conference the opportunity of passing, with 17 dissentients, a vote of confidence in the I.A.C. as its central negotiating body and of deprecating the formation of any new negotiating body as contrary to the interests of the medical profession as a whole. London withdrew a similar motion in view of the obvious need to support the I.A.C. at the present serious juncture.

Rate of Remuneration.

Dr. Brackenbury, on behalf of the I.A.C., moved a series of recommendations dealing with the rate of remuneration, which were accepted with practical unanimity in the following form:—

> This Conference reaffirms the opinion that 13*s.* 6*d.* is the lowest capitation fee that should be offered for an effective service, and asserts that there is no justification whatever for a *demand* that the arbitration award of 11s. should be lowered.
>
> This Conference recognises the force of the "appeal to citizenship" made by the Minister of Health to insurance practitioners "to make some sacrifice for the common good in a great financial crisis"; is willing to urge practitioners to respond to this patriotic appeal to any reasonable extent consistent with the interest of the public health; and asks the Government to discuss with representatives of the profession the best means of carrying this into effect.
>
> This Conference authorises the I.A.C. to consider with the Government (*a*) a rebate of 1*s.* on the present capitation fee; (*b*) any other relevant financial questions except that of mileage; (*c*) the date at which the new arrangements should come into effect; (*d*) the duration of such arrangement; and agrees to support any arrangement that may be arrived at.
>
> That the measure of success which has attended the experiment of providing medical benefit under the National Health Insurance Acts system has been sufficient to justify the profession in uniting to ensure the continuance and improvement of this system.
>
> This Conference, though of opinion that the Insurance Acts should be allowed to work during a number of normal years with such incidental improvements only as experience proves necessary, before any reliable conclusions can be drawn as to their effect on public health, would willingly take part in any wide inquiry into the working of those Acts that may be thought desirable, but suggests that any inquiry concerned with medical benefit should not be entered upon until April, 1922, at the earliest, that being the date at which the new regulations will have been two complete years in operation.
>
> That the I.A.C. be authorised to take immediate steps to see that the profession is so organised as to take any such united action as may be found necessary.

In moving these recommendations, Dr. Brackenbury said that it was not the first time that a patriotic appeal had been made by the Minister of Health to the medical profession which had already made sacrifices greater than those of any other section of the community. Other contract practice might also suffer concurrently with any lowering of the capitation fee, and the prevalent unemployment caused medical men to suffer also in other capacities. The decision was not for the medical profession alone to make, for medical benefit had become deeply rooted in the social system of the country.

These recommendations were submitted to Sir Alfred Mond during a recess in the Conference by a deputation including the I.A.C. and three members nominated directly by the Conference—viz., Dr. H. J. Cardale (London), Dr. J. A. Macdonald (Taunton), and Dr. D. F. Todd (Sunderland). The reply of the Minister was to the effect that he could not alter the suggested reduction of the capitation fee to 9s. 6*d.*—he had indeed been pressed to make it 8*s.*—but that he was prepared to guarantee its maintenance for two years and to discuss the date from which the reduction should become operative and the possibility of regarding it as a rebate and not a reduction of the basic fee.

After discussion the Conference agreed, with 13 dissentients, to instruct the I.A.C. to accept the Minister's offer "on grounds of citizenship."

Records.

The Conference, after accepting the recommendation of the I.A.C. that the *form* of record should remain as at present, with certain trifling verbal alterations, decided warmly that the obligation to enter on it the dates of all consultations and visits was irksome and unnecessary. Should this obligation be withdrawn, no exception would be taken to entering the date of initial attendance and the dates of issuing first and final certificates of incapacity, along with an appropriate clinical note. The proposal by Yorkshire W.R. of a single daily record card to last for a whole year, and to show the massed total of all services rendered during that period, met with a sympathetic reception. Apart from obligation it was admitted that the present form of record afforded practitioners desirous of making clinical notes a convenient means for so doing. The need for prompt transmission of records on request was again impressed on practitioners by their representatives.

Transfer of Practices.

It was agreed by overwhelming majority to press again for the withdrawal of the present regulations affecting the transfer of practices on death or retirement of the practitioner, and to do so on the lines indicated in the I.A.C.'s report. The right of an insured person to take this opportunity of making a fresh choice is freely admitted as well as the justice of making him aware of his right. But the I.A.C. contends that it is quite consistent with this right that insured persons who have not made a new choice within a reasonable period should be transferred to the successor's list as from the date of decease or retirement. The proposal is that on the decease or retirement of a practitioner the insured persons on his list would, as now, be informed of their freedom to make a fresh choice and of the willingness of the successor to the practice to accept them. A month before the first day of the next quarter but one, those who had not exercised their right would be further informed that unless they did so within a month they would be assigned to the successor. The patient, if for any reason dissatisfied, would thereafter be able to effect a change by giving notice to his insurance committee, the I.A.C. being prepared to agree to a simplified method of transfer, either at the quarter or forthwith by sanction of the allocation subcommittee. On this matter the Conference was evidently as united as on that of remuneration.

Defence Trust.

A report from the trustees of the National Insurance Defence Trust was received and approved. That fund had now been subscribed to by 101 out of a total of 197 panel committees, while 33 other committees had promised their support. A sum of £1300 had been received or promised during the year, bringing the fund up to a total of about £21,000. At the Conference itself, a considerable number of committees who had not so far supported the Trust expressed, through their delegates, willingness to do so. Dr. Brackenbury reported that it had already proved possible to make grants to certain panel practitioners who had suffered from their adherence to resolutions passed at a previous conference.

Bengal Board, F. Dec. 11, 1843; d. Bath, Oct. 17, 1853. Lunn, Wm., F. Aug. 26, 1844; Hull; d. 1866–67.

"SUNDAY CLOSING" AT BRITISH SPAS.

To the Editor of THE LANCET.

SIR,—An interesting paragraph in your last issue (p. 884) is a welcome reminder that the Federation of British Spas is doing good work. In the matter of the Sunday closing of bath establishments I cannot help hoping—although by no means a conservative in such matters—that they will adhere to the traditional British custom. Playing with what is after all serious treatment by week-end visitors ought not to be encouraged. We are now fully aware that the action of medical baths is gradual and cumulative and requires many days. And I think few spa physicians will assert that these ought to be given seven days in the week; or that the bath attendants during the busy season do not require a weekly respite from their responsible duties.

It is true that many years ago a Viceroy of India, since deceased, induced me, as his days (of treatment) were numbered, to obtain for him a Sunday bath in the most sabbatarian of British spas, but I am not sure that it benefited him, and it was certainly injurious to the health of the community. The recourse to the springs on Sundays is quite another matter, and religious sanction might be claimed for it and surely for music also.

As a strong believer in the intrinsic merits of the British spas, I welcome the efforts of the Federation to assist and coördinate their progress.

I am, Sir, yours faithfully,

London, Oct. 24th, 1921. R. FORTESCUE FOX.

HAIR-BALLS OF THE STOMACH.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Oct. 15th Dr. I. J. Davies, of Cardiff, gives an account of two recent cases of hair-ball or hair-cast of the stomach with an interesting analysis of 108 recorded cases. I should like to take this opportunity of briefly describing a case (not previously published) upon which I operated about 20 years ago.

The patient was a female child aged 2½ years admitted under my care to the East Suffolk Hospital. She was a persistent hair-eater; she would greedily devour portions of any rug, mat, or woollen garment such as a vest, which she could get hold of, and had torn off and swallowed most of her own hair. On examination a mass could be felt quite easily in the stomach; it was freely movable, having the shape of a cast of the interior of the organ. I operated, making a long incision on the anterior surface of the stomach midway between the curvatures and extracted the hair-cast. The stomach was closed with a double row of Lembert sutures, and the child made an uneventful recovery.

The hair-cast removed was of the shape and appearance shown in Fig. 3 in Dr. Davies's paper. Sir A. Mayo Robson asked me to give it to him for the Museum of the Royal College of Surgeons of England, where I believe it is at the present time. The case is, I think, worth recording owing to the extreme youth of the patient and the fact that it was diagnosed before operation and successfully removed. I have heard nothing of the subsequent history of the case.

I am, Sir, yours faithfully,

Ipswich, Oct. 18th, 1921. HERBERT H. BROWN.

are amenable to this therapy. Combination with small doses of iodine was found very beneficial, especially in the restoration of sight.

The New Institutes of Neurology and History of Medicine.

In spite of the difficult economic situation, two new institutes have lately been added to the large number of special departments of medical study in Vienna. In 1882 Prof. Heinrich Obersteiner began an agitation for accommodation for the study of neurology and of the morbid histology of the brain. It took him 23 years to obtain a few rooms and a small annual grant from the Government. Just before the outbreak of war a special building was at last allotted to his department, but the internal furnishing was only very recently completed. The institute contains spacious work-rooms, a class-room seating 100 pupils, a chemical laboratory, an aseptic theatre for animal operations, and housing for the animals, birds, and fishes used for experimental purposes. The library compiled by Prof. Obersteiner contains more than 50,000 volumes, and the department possesses one of the finest microtomes in the world, a gift from the Rockefeller Institute, but the unrivalled collection of microscopic specimens of the normal brain and cord is the proudest boast of the new institute. Many glass utensils, chemicals, &c., are still, however, lacking; the yearly Government grant is 1500 kronen, now worth about five shillings.

The Institute of History of Medicine owes its development to the persistence of Prof. Max Neuburger, who has striven for its foundation for 15 years. This institute is now housed in the former military surgical academy. The medical museum in this building illustrates the development of the Vienna Medical School during the past 150 years, and contains amongst other objects a unique collection of surgical instruments, given to the Medical Faculty of Vienna by the Emperor Joseph II. in 1785. The first stethoscope constructed by Laennec, the first ophthalmoscope of Helmholtz, and numerous letters, pictures, and documents pertaining to the old Vienna schools of medicine, are amongst the objects of historic interest in this museum.

Oct. 7th.

CZECHO-SLOVAKIA.

(FROM OUR OWN CORRESPONDENT.)

A Temperance Measure.

Deputy Holitcher has introduced a Bill into Parliament by which the sale of alcoholic drinks to persons under 18 years will be prohibited in bars and saloons. Every saloon keeper will be compelled to ask for documentary evidence if he suspects his customer to be within this age limit. The Bill has the support of all the Socialist parties, but there is strong opposition to it from the interests which stand behind the large brewing companies. The measure may be considered as the first results of the efforts of the Czecho-Slovak Temperance Union; the present time is particularly favourable for its introduction, as high war prices have greatly reduced the consumption of alcoholic liquor.

Tuberculosis Survey.

Dr. Jaroslav Hulka has just completed, under the auspices of the Ministry of Health, an extensive tuberculosis survey of Czecho-Slovakia. The survey contains figures which throw much light on the hitherto unknown situation of the country with regard to tuberculosis. It appears that out of a population of 13½ millions, about 48,000 people die of tuberculosis every year in the Republic. The tuberculosis death-rate per 100,000 for 1919 was 278 (all forms). The death-rate began to decline in the year 1886 and since then has fallen 38·3 per cent. Czecho-Slovakia occupies the fifth place in the series of States with a high tuberculosis mortality, being surpassed by Hungary, Serbia, Finland, and France. Thirty-five per cent. of the deaths in the working ages—i.e., 20–60—are caused by some form of the disease. This figure compares very unfavourably with the 10 per cent. rate in England. During the war the tuberculosis death-rate had risen 25 per cent. by 1916, remained at the same level during 1917, and reached its peak in 1918, the influenza year, showing an increase of 37 per cent. on the 1913 figures. Since then it has fallen rapidly. There are 58 public dispensaries in Czecho-Slovakia and 11 others privately owned by physicians; there are also 18 preventoria and sanatoria for children, 19 sanatoria for adults (3 of them military), and 11 tuberculosis hospitals. The total beds in all these institutions approximate 3500. The survey will be published by the Ministry of Health with an English summary.

Venereal Diseases Course.

The Section of Social Diseases in the Ministry of Public Health and Physical Education has organised a Venereal Diseases Course at the University of Prague. The course will consist of 50 lectures given by physicians sociologists, teachers, and lawyers. The number of persons attending has been limited, and the list has been closed for some time. The education of children in sex matters will be especially emphasised. The course has aroused so much interest that it will be repeated in December.

Oct. 14th.

Obituary.

EDWARD OWEN DALY, M.A., M.D. OXON., M.R.C.P. LOND.

Dr. E. O. Daly, who died at his residence in Hull on Oct. 18th at the age of 66, was the elder son of Dr. Owen Daly, honorary consulting physician to the Hull Royal Infirmary. He was educated at Cheltenham, University College, Oxford, and studied medicine at St. George's Hospital, where he afterwards acted as house physician and as assistant medical registrar. He qualified L.S.A. in 1880, and subsequently graduated M.A., M.D. Oxon., becoming also M.R.C.P. in 1884. In 1885, shortly after starting practice in Hull, he was elected honorary physician to the Hull Royal Infirmary. Later he became a consulting physician to that institution and to the Grimsby District Hospital, being also physician to the Hull and East Riding Convalescent Home and other institutions. In 1890 he was President of the East Yorkshire and North Lincolnshire Branch of the British Medical Association, a post which his father had held on two previous occasions. In 1902 he was President of the Hull Medical Society, and always gave of his best to both the Society and the Association. He contributed several articles to neurological journals, and had a profound knowledge of medical literature; his professional opinion was much sought after over a wide area. In questions of the day he was always interested, although he had no strongly marked political bias. In 1882 he married a daughter of the late Vice-Admiral E. P. B. von Donop. His married life was extremely happy, but a little more than two years ago he was severely shaken by a family bereavement, and of late his failing health was evident to his friends. The number of medical men who attended his funeral in Rowley churchyard bore witness to the respect in which Dr. Daly was held by members of his own profession. He is survived by his widow and two sons, both of whom have attained the rank of major in H.M. Regular Army.

ROYAL PORTSMOUTH HOSPITAL.—The sum of £10,000 has been allocated to the Portsmouth Hospital from the local War Memorial Fund. The unveiling by the Mayor of the memorial stone in the new gateway, which forms part of the scheme, took place on Oct. 19th, in the presence of a large gathering. Extensive improvements to the hospital buildings are in progress.

Medical News.

University of Cambridge.—At examinations recently held the following candidates were succesful:—

Examination for Diploma in Psychological Medicine.

Part I.—Mervyn A. Archdale, Douglas N. Hardcastle, Simon Kelly, Ralph A. Noble, and William D. Wilkins.

Examination in Sanitary Science.

The following have passed both Parts of the Examination:—

William Buchan (distinguished in Bacteriology), Dagmar Florence Curjel (distinguished in Practical Chemistry), Munohar Lal Dhir, Joseph H. Fairweather (distinguished in the principles of Hygiene and Bacteriology), Robert French (distinguished in the principles of Hygiene and in Practical Chemistry), William S. Gross, Bertram C. Haller, William J. G. Henderson, Godfrey W. Mitchell, Parasurama Parthasarathy, K. Raghavendra Rao (distinguished in the principles of Hygiene and in the Application of Sanitary Science), Henry Roger, George W. Shore, Isabel S. Thomson, Alandur Tirumalaiya, Edwin L. Warner, Robert Welch, and William L. Yell (distinguished in the principles of Hygiene).

University of Edinburgh.—At the graduation ceremonial held on Oct. 22nd the following degrees were conferred:—

Bachelor of Medicine and Bachelor of Surgery.—W. N. J. Chapman.

Diploma in Psychiatry.—Rachel M. Barclay.

University of Glasgow.—The following degrees were conferred on Oct. 17th:—

Bachelors of Medicine and Bachelors of Surgery.—Alice A. Alexander, Edith A. Allan, Mary Baird, Muriel C. S. Balfour, John J. Black, Alexander L. Brough, George Brown, Malcolm Brown, Muriel J. Brown, Duncan S. Buchanan, Albert J. G. Caporn, Daniel F. Cappell (with honours), Christabel L. M. Charlesworth, Alexander Chisholm, Jessie D. Christie, John Connal, David F. Craig, Margaret B. C. Craig, John G. Craik (with commendation), Elizabeth M'Vean J. Currie, James S. Currie, Alisdair C. Dewar, Joseph Dewar, Vina C. MacKay Donaldson, Arthur M'Donald Douglas, Mungo Douglas, Robert K. Duguid, James A. Dunlop, Andrew Gibb, Margaret E. Gibson, Mary D. Gilmour, Christina Gray, Alexander H. Greig, Beryl Grieve, John A. Hamilton, John K. Holmes, Benjamin Isaacs, Susan M. S. Jamieson, Frederick J. Kitt, Frances B. C. Livingston, Elizabeth K. B. Lockie, John M'Dougall, Edith M. F. M'Gill, Janet S. S. Mackay, William B. M'Queen, Ashie Main, Thomas D. Marshall, David Meikle, Nathan Mellamed, Hettie M. W. Miller, Malcolm J. Miller, Ian Murray (with commendation), Edith M. Neilson, Margaret R. Oulton, Catherine A. B. Pettigrew, Annie G. Pollock, Alexander H. Rankin (with commendation), Annabella A. Reid, Enid A. Robertson, Ian MacRae Sandilands, Jessie G. Service, Marion Smellie, Alexander Smith, Charles M. Smith, Margaret Sproul, Janet F. Steel, Donald Stewart, Jane W. Stocks, Helen Y. Stoddart, John M'Laughland Strang, Eva M. Sturrock, Hugh V. Sweeney, Dorothy B. Thomson, Edith I. Thornley, Robert R. Waters, Charles M. Whiteford, Janette R. Wilson, John Wilson (with commendation), Elizabeth M. Wyllie, John Young, and John Yule.

Mr. James R. Learmonth, who graduated on July 18th, 1921, gains the Brunton Memorial Prize of £10, awarded to the most distinguished graduate in medicine of the year.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.—The following candidates have passed the Triple Qualification Examination:—

Third Examination.

Oliver H. D. Oliver, Bruce F. Home, Daniel Maximos, Harry G. Triay, David R. Paterson, Wilhelmina C. Storrie, Johannes J. Malan, Samuel I. T. Wills, Annie F. Perry, Alexander L. Tinto, and James H. Murrell.

Pathology.—Hervey Anderson, Patrick Murray, James Kirkness, and Arthur W. H. Noble.

Materia Medica.—Charles J. Coventry, Oswald L. Shearer, Arnold Raff, and Leslie L. Armstrong.

Final Examination.

Vadakath Padmanabha Menon, Joseph Butler Dobson, Henry Ponnampalam Samuel, Hyman Penn, Gerrit Johannes Lamprecht, Grace O. D. Evans, John I. Hagard, Pauline Figdor, Jatindra Kumar Sen, Herbert W. Amyes, Peter E. Malloch, Lee Ee Liat, Stanley C. Alcock, Frank Walwyn, William Campbell, Leo H. Peries, John B. O'Neill, and Albert R. Rellum.

Medicine.—Edward J. Allan, Arthur R. Lambie, Arthur S. Wickremesinghe, and Parmanand Madan.

Surgery.—Andrus M. Samarasinghe and Jemima M. McKechnie Calder.

Midwifery.—Andrus M. Samarasinghe, Edward J. Allan, Arthur R. Lambie, Adriaan V. Bergh, Lionel R. Bergson, Parmanand Madan, Sayed Ghaleb, Mohamed Shafie Hassen, Jemima M. McKechnie Calder, and Frederick P. Lisboa-Pinto.

Medical Jurisprudence.—Lilian M. Williams, Matthew Burn, James M. Crombie, Andrew A. Dewar, Wilson O. Rodrigo, James A. McElroy Evers, James M. McInnes, John J. Mann, Israel Rostowsky, Otto Popper, Thomas J. Muir, Elizabeth Clark, and Isobel Reid.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held on Oct. 19th Sir David Wallace was elected President for the ensuing year, Dr. George Mackay Vice-President, and Mr. Alexander Miles secretary and treasurer.—Mr. John Smith Fraser was awarded the Liston Victoria Jubilee Prize of £100 in recognition of his work on the Pathology of the Internal Ear and its bearing on the Surgical Treatment of that organ.—The following candidates, having passed the requisite examinations, were admitted Fellows:—

Catherine E. Anderson, Pauchanan Chatterjee, Patrick A. B. Clark, James McMurray Cole, Peter C. Davie, Thomas A. J. Duff, Ernest C. Dunlop, Henry H. Elliot, George D. Fairley, Alec T. Gibb, Arthur H. Guymer, John J. Kearney, Oswald F. Lamb, Gordon B. Lowe, Hugh E. McColl, John R. MacNeill, George Nicholson, Frank C. Ormerod, George R. B. Purce, Jotindra Mohan Rakshit, Cecil G. Richardson, William S. Robertson, John Scott, and Gilbert I. Strachan.

The following candidates, having passed the Final Dental Examination, were granted the Diploma L.D.S. R.C.S. Edin.:—John M. Elliot, Douglas G. Munro, Michiel Josias de Kock, and Peter J. B. Dyce.

University of Manchester.—The following appointments have been made: Dr. R. A. Webb, Demonstrator in Pathology; and Mr. J. H. Blackaby, B.Sc., Assistant Lecturer in Physics. The following awards have been made:—Junior Research Fellowship in Public Health: Dr. William Stott; Dalton Chemical Scholarship: Mr. L. R. Ridgway, B.Sc.—The annual dinner of the past and present students of the Manchester University Medical School will be held at the Midland Hotel, Manchester, on Wednesday, Nov. 9th, at 7 P.M. The president will be Dr. F. Craven Moore, and the vice-presidents Dr. D. Dougal, Dr. J. F. O'Grady, and Mr. J. Morley. Tickets, price 15*s.* 6*d.*, can be obtained before Nov. 5th from Mr. W. Geraghty, hon. secretary, at the Medical School.

University of London.—Dr. W. B. Tuck has been appointed to the University Chair of Chemistry tenable at Middlesex Hospital Medical School. Dr. Tuck was in 1908 appointed a member of the teaching staff of University College, London, and after lecturing during the absence of Dr. Kellas at Middlesex Hospital Medical School was appointed lecturer in Chemistry at that School.

Dr. Charles Bolton, F.R.S., of the Graham Research Laboratories at University College, has been awarded the William Julius Mickle Fellowship of £200 in recognition of the important work in experimental medicine which he has carried out during the past five years.—Mr. H. J. Waring has been appointed to represent the University at the centenary celebrations of the Faculty of Medicine of the University of Montpellier on Nov. 5th.

Association of Infant Welfare and Maternity Centres: Workers' Section.—A conference will take place at 8 P.M. on Monday, Nov. 7th, at 14, Salisbury-street, Lisson-grove, London, N.W., when Miss Mildred Ransom will speak on the Professional and Business Women's Hospital League. On Tuesday, Dec. 6th, at 8 P.M., at the same place, Lady Barrett will open a discussion on Birth Control. Medical men or women willing to address the section at one of the 1922 conferences on some subject of vital interest to infant welfare workers are asked to communicate with the Hon. Treasurer, Mrs. M. C. D. Walters, 105, Addison House, Grove End-road, London, N.W. 8, or the Hon. Secretary, Miss S. Elliott, St. George's House, 220, Cable-street, London, E. 1.

Society of Medical Officers of Health: Annual Dinner.—The annual dinner was held on Oct. 21st at the Café Royal, Regent-street, Dr. W. J. Howarth, the President, being in the chair. There was a large attendance of Fellows and members and the guests included the Bishop of London, Prof. C. S. Sherrington, Sir Aston Webb, Sir Anthony Bowlby, Sir George Newman, Mr. J. W. Pratt, M.P., Sir Philip Magnus, M.P., Sir Arthur Robinson, and Dr. T. W. H. Garstang (Chairman of the Public Health Committee of the British Medical Association). A letter was read from Sir Alfred Mond, M.P., Minister of Health, regretting his inability to be present. Mr. J. W. Pratt proposed the toast of the Society of Medical Officers of Health. He said that before entering Parliament he was a member of the Corporation of Glasgow and of its health committee, and had realised how much it had meant to Glasgow to have had in the last 60 years such a succession of eminent M.O.H.'s. In that time the death-rate of the city had been halved and twice halved, and this was largely due to the labours of these men, who were not only expert advisers, but patient and persistent pioneers in the path which the community now sought to follow. He referred to the recent action of a council in discharging a woman medical officer on her marriage, and hoped that no one, whether man or woman,

"Audi alteram partem."

THE ROLL OF THE FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—May I ask you to give publicity in your columns to the enclosed list of some 250 names of Fellows of the Royal College of Surgeons of England, whose biographies are at present very scanty, if not wholly lacking? It is reasonable to hope that descendants, relatives, or friends of these gentlemen are living who would be able to give information as to them, so that they may be worthily included in the Roll, which at present numbers over 2400 biographies, or references to biographies, of Fellows deceased since 1843. I shall be glad to forward a copy of such facts as I have been able to obtain in the case of any given life to those applying to me by letter at this library.—I am, Sir, yours faithfully,

VICTOR G. PLARR,
Librarian, Royal College of Surgeons of England.
Lincoln's Inn-fields, London, W.C., Oct. 17th, 1921.

ENCLOSURE.

Abbey, John, Fellow (F.) June 28, 1855; practised (p.) Wellingborough; died (d.) ? 1865. Acheson, Johnston Hamilton, Surg. R.N., F. Aug. 26, 1844; d. July 8, 1864. Adolphus, Sir *Jacob, F. Parliamentary Intelligence.

HOUSE OF COMMONS.

Wednesday, Oct. 19th.

Medical Appointments at the Post Office.

Sir Walter de Frece asked the Postmaster-General if, in making any appointment of a medical officer to the Post Office, he would ensure that preference was given in every case to applicants who had served in the war; and in how many cases of recent appointments this had not been done.—Mr. Kellaway replied: In making an appointment as medical officer to the Post Office regard is paid to service with the forces; but consideration has also to be given to other factors, such as professional qualifications and length of residence in the district. There are no records available which would enable me to reply to the second part of the question.

Thursday, Oct. 20th.

Guardianship of Infants Bill.

Viscountess Astor asked the Prime Minister whether he could give an assurance that time would be given this Session to pass the Guardianship of Infants Bill through its final stages.—Mr. Lloyd George replied: In view of the definite assurance given by the Leader of the House on August 10th last that the only legislation to be taken would be that which necessitated the calling together of the House, I regret it will not be possible to deal with this Bill during the present sittings, which are only undertaken for the purpose of dealing with the problem of unemployment.

Milk for Infants and Mothers.

Viscountess Astor asked the Minister of Health whether he had received any protests concerning his decision to reduce the Government financial aid to local authorities for the provision of milk to infants and mothers; and whether he could reconsider the matter so as to give once again half the cost in cases where the medical officer to the local authority issued a certificate of need or where some other suitable safeguard against unnecessary expenditure was provided.—Mr. Myers asked the Minister of Health if he was aware that there was resentment on the part of the local authorities of the country towards the letter from his department which called upon them to keep separate accounts of the milk which were given free or below cost price to necessitous cases under maternity and infant welfare regulations and intimated that the State grant upon this part of the work was to be reduced from 50 to 5 per cent.; and whether, having regard to the good work which had been and was being done by the service, the reduction of the infantile death-rate which had been effected, together with the hardship which would be imposed upon poor people, the adverse effect upon infant life, and the added burdens to the local authorities under the conditions of the circular, he would withdraw the circular and restore the 50 per cent. grant for the whole of the infant welfare service.—Captain Coote asked the Minister of Health whether he had recently reduced the contribution payable by him to local authorities for the provision of milk to mothers and infants from 50 to 5 per cent. of the cost; whether he was aware that this reduction coincides with the beginning of winter, when milk was dearest, and with widespread distress owing to unemployment; what economy he was effecting by this reduction; and whether it could be secured in a less disastrous way.—Sir A. Mond replied: The very great increase in this service by local authorities has caused the estimate of the Government grant during the financial year already to be exceeded, and on strictly financial grounds severe reduction is entirely justified. But in view of the commitments of local authorities during the financial year and the distress existing from the extent of unemployment, I have decided that the 50 per cent. grant for milk supplied free or at less than cost price under the conditions laid down in Circular 185 will be continued until the end of the financial year.

Sickness among Children.

Mr. Leonard Lyle asked the Minister of Health if his latest reports showed any increase of sickness, especially among children, due to under-feeding or semi-starvation resulting from short time and unemployment.—Sir A. Mond replied: I cannot say from the information at my disposal that there has been an increase of sickness among children as a result of short time or unemployment.

Unemployment and Sick Insurance Benefit.

Mr. John Davison asked the Minister of Health whether, in view of the fact that large numbers of unemployed persons would be thrown out of the national health insurance benefit in consequence of arrears of contributions due to unemployment, he would take steps to exempt unemployed persons from national health insurance contributions during the present emergency.—Mr. William Thorne asked the Minister of Health if he was aware that large numbers of unemployed found that, although when in work they were compelled by law to insure themselves against sickness, now that they had been out of work for 12 months they had lost the right to all sick pay, even though they might have contributed in full since the Insurance Act was passed nine years ago, owed no arrears for periods of unemployment, and had never received any benefits; whether it was the intention of the Government to set matters right by passing a one-clause Act restoring to workers the right to remain insured against sickness during unemployment on having made proper payment for that purpose; and if he was aware that all the approved societies had entered a most emphatic protest against such men being deprived of their sick pay under the Health Insurance Act.—Sir A. Mond replied: I am aware that the provisions of the National Health Insurance Acts relating to the cessation of insurance on ceasing employment cause some hardship in special cases in the present abnormal conditions of prolonged unemployment, and the question of taking steps to meet this situation is at present under consideration.

Appointments of Medical Referees.

Sir Walter de Frece asked the Minister of Health whether he would undertake in future to give preference to all candidates applying for the post of medical referee who had served in the war, even if their absence from home in the service of the State naturally gave them a shorter record of home service in the district.—Sir A. Mond replied: In making appointments to the post of medical referee preference is given to men who have served in the war, other things being equal, but with due regard to the fact that many practitioners who did not serve in the armed forces had applied for such service and had been kept at home by the decision of the competent authorities that their services were indispensable for the needs of the civil population.

Construction of Roadway to Wingrove Hospital.

Mr. Grattan Doyle asked the Minister of Health whether he was aware that the Newcastle-upon-Tyne Board of Guardians, having received his consent to construct a roadway to their Wingrove Hospital and to employ on the work as much unskilled labour as possible from able-bodied unemployed men in receipt of assistance from the guardians, made application through the local authority to the Unemployment Grants Committee for a grant towards the expenditure incurred by them upon the labour directly employed, and that the Unemployment Grants Committee had declined to make a grant merely on the grounds that the men were not engaged through the local labour exchange, notwithstanding that the guardians' action was intended to save the payment both of unemployment benefit and Poor-law relief, all such labour employed being already registered at the labour exchange; and, if so, what action he proposed to take in the matter in view of the distressing prevalence of unemployment in Newcastle-upon-Tyne.—Sir A. Mond replied: This matter was dealt with by the Unemployed Grants Committee, and I understand that they refused a grant because the guardians failed to comply with the condition requiring preference to be given to unemployed ex-Service men, but I am in communication with the committee on the matter.

Monday, Oct. 24th.

Testing Clinical Thermometers.

Mr. Hailwood asked the President of the Board of Trade if he was aware of the inaccuracy of a large percentage of clinical thermometers; and would he take steps to introduce some method of test and certificate of correctness.—Mr. Stanley Baldwin replied: This is a matter which can only be dealt with by legislation, and I would remind my hon. friend that a Bill to require the testing of clinical thermometers was introduced by the Government earlier in the session, but was not proceeded with owing to lack of time. I hope to reintroduce the Bill next session. In the meantime I am glad to say that most British manufacturers of clinical thermometers are voluntarily having their products tested at the National Physical Laboratory.—Mr. Kiley asked the President of the Board of Trade whether, in the case of a person purchasing a clinical thermometer and not being content with the maker's guarantee and desiring to have the instrument tested, it was possible for the individual to take the same to the national laboratory, Kew, and have it tested for a few pence; and, if this was not so, could he make arrangements for it being done in such cases where it was desired.—Mr. Stanley Baldwin replied: Single clinical thermometers can be tested at the National Physical Laboratory on payment of a fee of 1s. 6*d.*; the fee when large quantities are submitted is 3*d.* per instrument. This arrangement has been in existence for several years.

THE COMPOSITION OF CIGARETTES.

To the Editor of THE LANCET.

SIR,—*Recently an American friend sent to me the* following paragraph from the *Spartanburg Journal* of Sept. 20th :—

Sept. 20, 1921. The Board of Managers of the Anti-Cigarette League in Chicago announce that they have procured the results of investigations of American medical laboratories and the London *Lancet* Laboratory which disclosed that, in addition to nicotine, cigarette and tobacco smoke were found to contain prussic acid, acrolein and carbon monoxide. "These gases were used in large quantities in the late World War to kill soldiers," *adds the announcement.* "There were also found several other deadly poisons, *including furfural, an irritating substance said to be about* 50 times as poisonous as ordinary alcohol."

As it refers to investigations of the Laboratory connected with your paper, I think that the paragraph calls for serious notice. I have read numerous articles in THE LANCET from 1899 to the present date on the question of whether or no cigarette and tobacco smoking affects the health, but I do not recollect having seen any reference, in such articles, to cigarette and tobacco smoke containing prussic acid, acrolein, furfural and the like, and I should be glad to know whether there is any truth in the statements, as to the results of your alleged investigations, made by the Board of Managers of the Anti-Cigarette League in Chicago. I am, Sir, yours faithfully,

Wembley, Middlesex, Oct. 18th, 1921. A. E. MAWN.

*** An analysis of the composition of American cigarettes was made in THE LANCET Laboratory at the end of 1899, and the report was published on Dec. 9th of that year. Its issue was determined by some remarkable statements in certain New York newspapers of paralysis, collapse, lunacy, and suicide stated to have been caused by cigarette-smoking. Our correspondent in New York purchased various brands of cigarettes in shops in New York City and sent them to THE LANCET Laboratory, while we purchased in London cigarettes of American manufacture, being in the majority of instances the same brands. The cigarettes were then subjected to close investigation, the percentage amount of nicotine being calculated as well as that of saccharine matters, opium, phosphorus, arsenic, mercury, copper, and other heavy metals. The paper, whose ratio to tobacco had been calculated, was subjected to the same scrutiny. Our examination showed that the allegations in regard to the presence of foreign poisonous materials in the cigarettes were entirely unfounded, save that in one instance there was bare evidence of a trace of copper in the paper. No reference was made in the report to the presence of prussic acid, acrolein, furfural, or the like. In an article on the toxic factors in tobacco in general, published on April 6th, 1912, acrylaldehyde or acrolein is mentioned among the irritating bodies which may be present in tobacco smoke. In a further article on the same subject the presence of furfural in minute quantities is noted in the tobacco smoke of certain cigarettes and smoking mixtures, and the chemistry of its presence is explained. The mention of furfural in the *Spartanburg Journal* is misleading. The poisonous character of this substance was alluded to in connexion with an investigation into alcohol.—ED. L.

THE HARVEIAN ORATION.

To the Editor of THE LANCET.

SIR,—Owing to an unfortunate printer's error (for which you are not responsible) in your issue of Oct. 22nd (p. 840) Malpighi is credited with the authorship of "De Sedibus et Causis Morborum"; it should, of course, be Morgagni. May I take this opportunity of asking those Fellows who have received uncorrected copies of the Oration kindly to correct the error, which occurs on page 32, line 1.

I am, Sir, yours faithfully.
HERBERT SPENCER.

Harley-street, W., Oct. 24th, 1921.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—There has recently appeared in the popular press an account of some cases of belladonna poisoning, and my name was mentioned in connexion with them. The account was published without my knowledge or consent.—I am, Sir, yours faithfully,

Limpsfield, Surrey, Oct. 12th, 1921. J. R. BENTLEY.

VICTOR HORSLEY MEMORIAL FUND.

A MEETING of the executive committee of the subscribers to the Victor Horsley Memorial Fund was held at 1, Wimpole-street, London, on Oct. 20th, with Sir CHARLES BALLANCE, K.C.M.G., in the chair.

Sir FREDERICK MOTT (hon. treasurer) presented a financial report stating that the amount of subscriptions promised was £1025, of which £875 had been paid into the bank. There was little doubt that the whole amount promised would shortly be paid, and it was probable that the interest on the deposit would be sufficient to defray the cost of printing and postage. The number of subscribers, exclusive of groups, is 229.

The following recommendations from the executive subcommittee were received and proposed for adoption by the Chairman :—

(1) That the Victor Horsley Memorial Fund be invested in the names of a Board of Trustees consisting of the President of the Royal Society, the President of the Royal College of Surgeons of England, the President of the British Medical Association, the Senior Physician of the National Hospital for the Paralysed and Epileptic (Queen-square), the Senior Surgeon of University College Hospital, in virtue of their office, together with Mr. Edward Robinson (the son-in-law of Sir Victor Horsley) and Mr. Edward J. Domville, one of the hon. secretaries of the fund, the vacancies caused by the resignation or death of either or both of these last named not to be filled up.

(2) That the trustees shall triennially appoint a lecturer to deliver a lecture in London, under the title of The Victor Horsley Memorial Lecture.

(3) That no limitation be placed on the trustees as to the country or profession from which the lecturer should be appointed, nor on the subject of the lecture to be delivered.

The resolution for the adoption of the recommendations was seconded by Sir WILLIAM ARBUTHNOT LANE, supported by Dr. GEORGE MURRAY, Dr. MARY STURGE, and Mr. W. G. SPENCER, and carried unanimously.

A vote of thanks to Mr. Domville for his services was carried by acclamation. It was resolved to close the list of subscriptions on Dec. 31st.

THE LATE DR. ELLERINGTON REED TURNER.—The death has occurred of Dr. E. R. Turner, of Kintore. Dr. Turner, who was a native of Brora, graduated M.B., C.M. at Aberdeen University in 1891. He took up general practice in Kintore 28 years ago. He was for several years Provost of Kintore, and at the time of his death was a member of the town council. He was also chairman of the late School Board, and a justice of the peace for the county. He is survived by a widow.

MEDICAL BENEFIT AMENDMENT REGULATIONS (No. 5), 1921.—These regulations make slight alterations in the rules for certification to meet certain difficulties, viz.: (1) The practitioner is asked to sign final certificates after the insured person has resumed work. This is met in para. 6, which allows a final certificate to be given for the second day, or in rural areas for the third day, after the date of the examination. (2) The absence of a suitable form of certificate in cases where the insured person is ordered a change at the seaside, or goes into a convalescent home. This is provided in the intermediate convalescent certificate. (3) The practice of certain practitioners of issuing more than one certificate without making a fresh examination of the patient. Para. 9 orders that "A practitioner having issued a certificate under these Rules shall not issue a further certificate without again examining the insured person, except that, if the original certificate is lost or mislaid, he may issue a duplicate, but in that case the form shall be clearly marked 'duplicate.'"

East London Hospital for Children and Dispensary for Women, Shadwell, E.—S. Asst. S. Asst. P.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—Asst. H.S. £150.

Great Northern Central Hospital, Holloway-road, N.—Two S.'s.

Worcester General Infirmary.—Res. M.O. £200.

The Chief Inspector of Factories, Home Office, S.W., gives notice of the following vacant appointments: Eyam (Derby), Rufford (Lancaster).

Births, Marriages, and Deaths.

BIRTHS.

Hall.—On Oct. 21st, at 1, Eslington-road, Newcastle-on-Tyne, to Margaret, wife of George Hall, C.M.G., M.D., M.R.C.P.,—a son.

Jackson.—On Oct. 15th, at Queen's Hospital, Sidcup, the wife of T. Jackson, L.R.C.P.E., L.D.S., of a son.

Sampson.—On Oct. 20th, at Sudbury, Ryde, I.W., the wife of Basil F. Sampson, M.C., M.B., B.S.Lond., of a son.

Savy.—On Oct. 23rd, at The Grange, Kingussie, Inverness-shire, the wife of Felix Savy, M.B., Ch.B., of a son.

Weston.—On Oct. 17th, at 23a, Connaught-street, Marble Arch, W.2, the wife of Bt.-Major T. A. Weston, M.B., B.C., R.A.M.C., of a daughter.

MARRIAGES.

Rowe—Matthews.—On Oct. 19th, at Seven Kings Wesleyan Church, Harold Ridges Rowe, L.D.S.Eng., of Queensland, South Africa, to Emma E., only daughter of Thomas M. Matthews, Pembroke-road, Seven Kings.

Vevers—Carpentier.—On Oct. 12th, at the Church of the British Embassy, Paris, Oswald Henry Vevers, M.R.C.S., L.R.C.P., to Geneviève Gabrielle Marie, only daughter of the late Julien Carpentier and the late Madame Bournisien de Valmont.

DEATHS.

Daly.—On Oct. 18th, at Albion-street, Hull, Edward Owen Daly, M.D.Oxon., aged 68 years.

Scarlett.—On Oct. 20th, very suddenly, at Higham's Park, Chingford, Essex, Ferdinand L. L. Scarlett, M.D., M.Ch., aged 70 years.

Steele.—On Oct. 22nd, the result of an accident, Richard Steele, M.R.C.S., L.R.C.P., of Willifield Way, Golders Green, and late of Peatling Magna, Leicester, aged 66 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, Oct. 31st.

SOCIAL EVENING: The first Social Evening of the Session will be on Monday, Oct. 31st, at 8.30 P.M., when Fellows and their friends will be received by the President, Sir John Bland-Sutton and by Lady Bland-Sutton. The President will deliver a short Address at 9 P.M. on Choroid Plexuses and Psammomas.

The Library will be open and various objects of interest will be exhibited. Music, light refreshments, and smoking.

MEETINGS OF SECTIONS.

Tuesday, Nov. 1st.

SURGERY: SUB-SECTION OF ORTHOPÆDICS: at 5.30 P.M. (Cases at 5 P.M.)

Cases will be shown by:

Mr. P. Maynard Heath: Resection of Upper End of Diaphysis of Humerus for Myeloma, and Replacement by Beef Bone Graft.

Mr. R. C. Elmslie: A Case of Congenital Absence of Sacrum.

Cases will also be shown by the President (Mr. Laming Evans), Mr. H. A. T. Fairbank, and Mr. W. Rowley Bristow.

PATHOLOGY: at 8.30 P.M., at the Laboratories of the Imperial Cancer Research Fund, 8–11, Queen-square, W.C. 1.

Dr. W. Cramer: Vitamins and Cancer Growth.

Dr. A. H. Drew: In-vitro Culture of Tissues in Artificial Media.

Dr. B. R. G. Russell: Carbohydrate Metabolism of Tumours

Dr. J. A. Murray: Experimental Tar-cancer.

Wednesday, Nov. 2nd.

SURGERY: at 5.30 P.M.

The opening paper of the session will be given by the President (Mr. Raymond Johnson) on Carcinoma of the Small Intestine.

Thursday, Nov. 3rd.

BALNEOLOGY AND CLIMATOLOGY: at 5.30 P.M.

Presidential Address by Dr. Hill Joseph: A Retrospect of a Quarter of a Century of Seaside Practice.

Members of the Section, with guests, will dine together at the Welbeck Palace Hotel, Welbeck-street, W., at 6.30 P.M. Those intending to be present are requested to send their names to Dr. C. F. Sonntag, 80A, Belsize Park-gardens, N.W. 3, not later than the last post on Nov. 2nd.

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.

Exhibits: Mr. A. E. Mortimer Woolf: A Specimen of Double-ruptured Interstitial Ectopic Pregnancy.

Dr. W. J. O'Donovan (introduced by Mr. Gordon Luker): A Gold Button Contraceptor.

Short Communication: Dr. G. Cranstoun: Cystic Adenoma of the Uterus.

Paper: Dr. R. L. MacKenzie Wallis: Glycosuria in Pregnancy.

Friday, Nov. 4th.

LARYNGOLOGY: at 4.45 P.M. (Cases at 4 P.M.)

Cases and specimens will be shown by Mr. Thomas Guthrie, Mr. E. D. Davies, Dr. Irwin Moore, Mr. G. W. Dawson, Prof. Shattock, Mr. Lawson Whale, Sir James Dundas-Grant, and others.

ANÆSTHETICS: at 8.30 P.M.

Mr. H. E. G. Boyle: Report on his visit as Official Representative of the Section to the first meeting of the Canadian Society of Anæsthetists at Niagara, and to the meeting of the American Society of Anæsthetists at Boston in June last.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

Wednesday, Nov. 2nd.—8 P.M. Opening Meeting.—Mr. A. A. Campbell Swinton: Wireless Telegraphy.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Museum Demonstrations in the Theatre of the College for Advanced Students and Medical Practitioners:—

Monday, Oct. 31st.—5 P.M., Prof. S. G. Shattock: Degenerations: Necrosis.

Friday, Nov. 4th.—5 P.M., Sir Arthur Keith: Specimens and slides illustrating various kinds of Disordered Growth at the Epiphyseal Line.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.

Tuesday, Nov. 1st.—5 P.M., Mitchell Lecture:—Dr. F. Parkes Weber: The Relations of Tuberculosis to General Conditions of the Body and Diseases other than Tuberculosis.

Thursday, Nov. 3rd.—5 P.M., Bradshaw Lecture:—Dr. Michael Grabham: Sub-Tropical Esculents.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Oct. 31st.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. Dr. Morton: X Ray Department. Dr. Simson: Diseases of Women. 5 P.M., Mr. Donald Armour: Practical Surgery. (Lecture I.)

Tuesday, Nov. 1st.—10 A.M., Dr. Robinson: Gynæcological Operations and Visit to Wards. Mr. Steadman: Dental Department. 12 noon, Mr. Sinclair: Gall-would be forced to remain unmarried as a condition of holding high office. Long before a Ministry of Health was talked of there was in every M.O.H.'s office the promise and prophecy of such a ministry. The Society of M.O.H.'s had a great influence on public opinion which was never more ripe for great advances along all paths of physical improvement. The President, in the course of his reply, said the Ministry was the Ministry of Health, and not the Ministry of National Health Insurance, and that money spent on preventive medicine was capable of much greater return than anything spent on curative medicine. Sir George Newman proposed the toast of "Pulpit, Parliament, and the Public Health." He said that these terms stood for the moral law or law of conduct, the law of the State, and the law of science. In the lean years that lay before them it was by the association of these three principles that they would commend the laws of preventive medicine to the English people. This had not yet been done, nor had the principles been practised. There was a vital and integral relationship between the character of a people and its public health. He associated with the toast the Bishop of London, whom he characterised as an ally of public health in the highest sense; and Sir Philip Magnus, who would always be remembered for securing fixity of tenure for M.O.H.'s, and who had that day been elected as an Honorary Fellow of the Society. The Bishop of London recalled his past experiences in association with public health at Bethnal Green and Fulham, and his present position as chairman of the Council for Public Morality of London. Sir Philip Magnus said that half of his constituency was composed of the medical and teaching professions, and that he represented more doctors than any other M.P. As the Bishop had claimed for the Church, so he claimed for teachers that they were colleagues of that Society, their common motto being *Mens sana in corpore sano*. Dr. F. E. Fremantle, M.P., proposed the health of the visitors. Prof. Sherrington, replying, said that to the pure scientist the vocation of the M.O.H. was perhaps the most attractive branch of practical medicine. The fruits of science were partly practical (like wireless telegraphy, or the rotatory hair-brush !) and partly theoretical (like relativity, or the nuclear structure of the atom). The M.O.H. was out for both kinds of result, and thus showed a real acceptation of the true faith of science. The President spoke in appreciation of the work of Captain Elliston, their executive secretary, during whose term of office their membership had increased from 600 to 1600. Dr. Herbert Jones proposed the health of the officers of the Society, and Dr. G. F. Buchan and Dr. R. A. Lyster replied.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the annual stated meeting of the President and Fellows of the College, held on Oct. 18th, the following officers were elected for the coming year:—President: Sir James Craig. Vice-President: Dr. N. M. Falkiner. Censors: Dr. N. M. Falkiner, Dr. J. A. Matson, Dr. W. G. Harvey, and Dr. R. A. MacLaverty. Representative of the College on the General Medical Council: Sir John Moore. Representatives of the College on the Committee of Management: Dr. Walter Smith, Sir John Moore, and Dr. T. P. C. Kirkpatrick. Treasurer: Dr. H. T. Bewley. Registrar: Dr. Kirkpatrick. Librarian: Mr. R. Phelps.—The St. Luke's Day service of the College—the first held since 1913—was held in the evening, when more than a hundred Fellows and guests dined together. Immediately before dinner, when the company had assembled, the Provost of Trinity College, the Right Rev. and Right Hon. Dr. J. H. Bernard, who had recently been elected an Honorary Fellow of the College, was introduced by the Registrar, Dr. T. P. C. Kirkpatrick, and admitted. Among the guests present at the dinner were the Archbishop of Dublin, the Lord Chancellor of Ireland, the Vice-President of the Royal College of Surgeons in Ireland, and the President of University College, Dublin.

UNIVERSITY OF SHEFFIELD: *Post-graduate Demonstrations.*—The series of post-graduate demonstrations arranged by the Faculty of Medicine for the Michaelmas term promises to be most popular. Already about 50 practitioners have applied to attend, and it is probable that more will join later. The subjects have been chosen after consultation with the local branch of the B.M.A. and the Panel Committee, whose advice and help to the Clinical Studies Committee of the Faculty has been valuable. On each day, twice weekly, two members of the staff give short demonstrations of about three-quarters of an hour each on their own special subjects. Demonstrations on pathology and physiology are included. The demonstrations are held at the Royal Infirmary and Royal Hospital, and a certain number on gynæcological cases at the Jessop Hospital for Women. The opening demonstrations were held at the infirmary on Oct. 12th, when Prof. A. M. Connell dealt with cases of fracture, and Prof. E. Mellanby discussed diets.

LADIES MEDICAL GOLFING SOCIETY.—The autumn meeting will be held at Oxhey Golf Club on Tuesday, Nov. 8th. Particulars may be obtained from the Hon. Secretary, Mrs. E. Laming Evans, 50, Seymour-street, London, W. 1.

ROYAL SUSSEX COUNTY HOSPITAL.—Princess Mary will visit Brighton on Nov. 22nd to open the additional branch of the Royal Sussex County Hospital's Nurses' Home. The Nurses' Home has been extended and admirably equipped at a total cost of £23,000.

ROYAL SOCIETY OF ARTS.—The opening meeting of the session will be held at John-street, Adelphi, London, W.C., on Wednesday, Nov. 2nd, when an address (illustrated by experiments) will be delivered at 8 P.M. by Mr. Alan A. Campbell Swinton, F.R.S., chairman of the council, on Wireless Telegraphy. On Nov. 9th, at 8 P.M., Mr. D. R. Wilson, secretary of the Industrial Fatigue Research Board, will address the society on the Work of the Industrial Fatigue Research Board and its Applications to Industry, Mr. William Graham presiding.

RONTGEN SOCIETY.—A general meeting will be held on Nov. 1st, at 8.15 P.M., in the Institution of Electrical Engineers, Savoy-place, Victoria Embankment, London, W.C. 2. The plaques awarded for the best collections of four prints submitted for the exhibition of radiographs in June will be presented, and the presidential address will be read by Prof. J. W. Nicholson, F.R.S. Members wishing to read papers or to show apparatus or lantern slides to the society are requested to communicate with the hon. secs.: Dr. E. A. Owen, D.Sc., the National Physical Laboratory, Teddington, Middlesex; and Dr. Russell J. Reynolds, 140, Harley-street, London, W. 1.

PROVISION FOR THE BLIND IN ROSS AND CROMARTY.—At a meeting of the Ross and Cromarty County Council, held on Oct. 20th, the finance committee reported on the conference held in connexion with the working of the Blind Persons Act. Subject to the approval of the Board of Health, it is proposed that the counties of Moray, Nairn, Inverness, Ross, Sutherland, and Caithness should combine in forming a joint scheme, under which provision could be made for blind persons within the area through the agency of the Northern Counties Institute for the Blind, and their outdoor society, and that each authority should contribute towards the total cost in accordance with the number of blind persons from their respective areas receiving benefit through the institute.

FIELD LABORATORY FOR FEEDING EXPERIMENTS. A few months ago the Sheffield Panel Committee allotted a sum of £1000 to the equipment of a field laboratory. The University has now acquired a site, and the work of building the necessary laboratories and animal houses is in active progress. The site chosen is on the west side of the city about two miles from the University. It is on the edge of the moors, nearly a thousand feet above sea-level. To those who only know Sheffield from passing through it in the train, it may be somewhat of a surprise to hear that within such short distance of the city and its smoke there should be grouse moors. Yet so it is, and at the site of the new field laboratory there is no sign of the smoke or sound of the noise of a great manufacturing centre. The laboratory will be under the immediate charge of Prof. E. Mellanby, and he and Mrs. May Mellanby will continue there the experimental work which has hitherto been carried on in the field laboratory at Cambridge.

ROYAL VICTORIA HOSPITAL, BELFAST: PRESENTATION BUST.—At a meeting held on Oct. 19th a presentation bust of Sir William Crawford, J.P., a former chairman of the board of management of the hospital, was placed in the King Edward Hall of the institution. The presentation was made on behalf of the subscribers by the Rev. W. A. Watson. In accepting the gift Prof. J. A. Lindsay, chairman of the board, spoke in warm terms of Sir William Crawford's services. He was chairman from 1901 to 1908, and again from 1914 to 1918, when he retired on grounds of health. He was assiduous in the discharge of his duties and took an active interest in all departments of the institution, while his unfailing courtesy earned for him the warm regard of all his colleagues. His period of office covered an important period in the history of the hospital—the epoch which coincided with the removal of the hospital from its former premises in Frederick-street to the present buildings. It was a matter for congratulation that, at a time when so many problems had to be faced, and such large financial responsibilities incurred, the hospital had had such a capable administrator and so wise a guide at its head. The present financial position of the hospital, so much more favourable than that of most of the great hospitals of the kingdom, owed much to his financial ability and judicious oversight. The bust was executed by Miss Acheson, a niece of Sir William Crawford, and is a faithful and pleasing likeness.

the bottom covered with a dirty-coloured, fœtid, firmly fixed, tattered necrotic coating. Pain still very severe. On the 16th, dressing with Fischer's fluid. On the 24th, ulcer much cleaner, pain almost ceased. On the 31st pain ceased, ulcer filling up with granulations. On April 23rd ulcer now filled up, granulations fresh. On May 21st ulcer reduced to half. On August 25th, ulcer healed, skin smooth and only slightly atrophic.

CASE 2.—"Kommunehospitalet" (Municipal Hospital), Copenhagen. Chr. H., male, aged 47; burns. On May 6th, on the fore side of the right thigh, near the groin, were found two ulcerations of about the size of a sixpenny-piece, with irregular, necrotic edges and sunk central part, covered with a yellowish-green necrotic tissue. Fischer's fluid prescribed. On the 8th the central parts of the burns almost on a level with the surrounding sound integument; necrosed tissue of the edges is partly cast off. On the 11th sores diminished; edges fresh with pinkish epidermis. On the 24th sores healed.

CASE 3.—Kommunehospitalet. T. E., male, aged 15; adenitis inguinalis, ulceration. Transferred from Ward 4, where he had been since Oct. 28th, 1919, under the diagnosis of ulcus penis, balanoposthitis acuta, right inguinal bubo. An incision had been made above and below the ligamentum, and a good deal of pus had been evacuated. The ulcer was treated with resorcin, lapis infernalis, iodoform, salicylic acid, sulphate of copper, and sublimate; the cavity persisting, he was removed to Ward 5 on April 7th, 1920. Physical examination showed nothing abnormal except ulcer in groin, of irregular shape with edges rolled up, being a good centimetre in depth. Skin cicatricial and red; ulcer only slightly tender. On April 8th, in probing the cavity two recesses were felt extending upwards and inwards, one for 2-3 cm., and the other for 2 cm. A V-shaped section was removed for microscopic examination. Plugging with iodoform gauze. On the 14th, only a little secretion; edges slightly infiltrated. On the 27th, still some secretion; superficial ulcer healing slowly. On the 30th, ulcers practically unaltered. Dressing with iodoform gauze. On May 8th, no retention; ulcers spreading on the surface. Dressing with Fischer's fluid. On the 10th a furuncle had appeared just above the symphysis. On the 12th *B. pyocyaneus* had appeared. On the 14th, the ulcers in the right groin had for the last six days been dressed with Fischer's fluid. At the beginning of that time there was a plum-sized cavity, and above it a filthy ulcer (8 by 15 cm.), flat, covered with rather flabby granulations; on this date cavity was filled up from its base, and only the size of an almond; granulations in both ulcers fresh and clean: new growth of epidermis progressing in a broad border from the edges. On the 17th healing constantly advancing; formation of new epidermis on superficial ulcer twice as broad as on the 14th; deep ulcer filling up well with granulations, and now size of kernel of a nut. On the 21st granulations growing rapidly, everywhere vigorous and clean; growth of epidermis advancing in a surprising manner; fresh epidermis seems especially vigorous and powerful; recess has further diminished. On the 25th large cavity completely filled up and almost healed. Superficial ulcer progresses with formation of epidermis like a fine veil over the granulations. Growth of epidermis seems slower than at first. On the 27th ulcers nearly healed. On June 11th ulcer healed, except a few spots the size of a pea. On the 14th ulcer healed; patient discharged.

CASE 4.—Kommunehospitalet, Copenhagen, Ward 5. M. B., male, aged 19, unmarried; burns on forearm. Admitted March 23rd, 1920. Five days previously had sustained burns, having fallen into a pail of charcoal whilst feeling ill (pleuritis). Burns on both legs and right forearm; below the elbow on the extensor side a burn of third degree, about 4 by 10 cm. On April 21st, record states that very considerable granulated skin defects had gradually formed below and around elbow. At bottom of defect nearest the ulna, bone denuded to extent of finger's breadth. On the 24th, under regional anæsthesia with novocaine-adrenalin, transplantation from the right thigh. Firm closing salt-water dressing; dressing changed. On May 1st, only a few islets of skin fixed on large ulcer; heavy secretion. On the 3rd, dressing changed. On the 5th, a few scattered patches left from the transplantation; cavity above upper part of ulna filling up. On the 8th, during local anæsthesia with novocaine-adrenalin another transplantation (Thiersch's method) performed on the remaining surfaces. Salt-water dressings. On the 14th the salt-water dressing had been shifted a few times; some patches adhered. On the 20th dressing with Fischer's fluid. On the 22nd, sores of considerably smaller extent; granulating surfaces fresh and slightly bleeding. On the 27th ulcer diminished wonderfully well and rapidly; new growth of epidermis appears particularly strong. On June 8th epidermis growing over nearly whole surface of sore; only three very small spots not yet healed. New growth of epidermis remarkably good and strong; all movements of elbow entirely free. Patient discharged. On the 11th, after ambulant treatment, sores completely healed.

CASE 5.—Private. H. K., male, married, aged 51. X ray, ulcerous. Seen on May 21st, 1920; during some years had suffered from "eczema" on right calf; treated successfully with X rays two years ago; owing to relapse the treatment was repeated last year. Received altogether five irradiations—dose unknown. Shortly after last irradiation diffuse reddening of irradiated area occurred early in December; later a deep painful ulcer developed, not perceptibily influenced by treatment during past six months. Pains so excruciating and persistent that he can only get a little rest by sprinkling sore with anæsthetics several times daily. On right calf a sharp-edged ulcer, about 6 by 6·5 cm. on surface and about 2 cm. deep, covered with soiled, yellowish-green foulness, through which spots of reddish tissue faintly seen. In circumference of ulcer five or six large blebs. Fischer's fluid used. On the 22nd pain considerably abated; anæsthetics not used. On the 23rd blebs spreading; patient admitted to Kommunehospitalet; discharged after a week for further treatment with Fischer's fluid. On July 3rd sore clean, and of smaller extent; patient free from pain, able to attend to his duties. On Oct. 15th sore the size of a shilling. On Nov. 10th, sore smaller, 2 by 2 cm.; bottom clean.

CASE 6.—X ray clinic of Kommunehospitalet. J. O., female, aged 62; ulcus cruris. On June 5th patient had been treated in the Policlinic for about ten weeks with boiled water, chloric lime-water, lapis, with no success; experimental treatment was therefore suggested. In the fore part of the right lower leg an irregular, filthy, undermined ulcer of the size of a penny, with excruciating pain. Treatment with Fischer's fluid. On the 10th sore cleaner, pain nearly ceased. On the 14th ulcer superficial, pain ceased. On August 6th ulcer healed. During treatment she has done her work as a charwoman. On Oct. 2nd patient seen; ulcer is still healed.

Remarks.

All these cases refer to patients with ulcerations that had either appeared quite refractory to previous treatments, or had only shown a slight tendency to heal. In every case the treatment with incitamin gave a particularly favourable result, and it cannot be disputed that the time of treatment was considerably shortened for these patients. Among these patients, and others whom I have treated, several were spared sojourn in hospital—a fact worthy of emphasis.

Case 3 showed a serpiginous ulceration in the right groin. At first a bubo was found which was incised above and below the ligamentum. In spite of six months' treatment with such different remedies as resorcin, lapis, iodoform, sulphate of copper, and sublimate, the cavity remained; the patient was transferred into the surgical department, where two abscesses were opened; but on the surface the ulceration spread. Fischer's fluid was prescribed. At that moment there was a cavity the size of a plum, and above it an unclean ulcer, covered with rather flabby granulations. Six days later the cavity was filled up from its bottom, and was only of almond size, while the new growth of epidermis was rapidly advancing. A week later granulation was proceeding with great rapidity, and the tissue was everywhere strong and vigorous. On the eleventh day the great cavity was entirely filled up, and after the lapse of five weeks the ulcer was healed. Ten days later the cure proved to be lasting.

Case 4 exemplifies very well that the new growth of epidermis in an ulcer can take place in a surprisingly quick manner when the latter is treated with incitamin. The patient had a large burn on his forearm, which remained practically unaltered for about a month. Graftings had been tried with no great result. Two days after incitamin dressings were begun the ulcers had diminished considerably, and a daily advance of the new growth of epidermis was noted. On the eighteenth day there only remained three very small spots, covered with epithelium. The patient was then discharged and treated ambulatorily; on the twenty-second day the ulcers were entirely healed with good and strong epidermis. Finally, it must be pointed out that epidermis formed during treatment with incitamin has always been particularly good and strong.

When ulcers were unclean, covered with necrotic tissue, and fœtid, they cleansed wonderfully rapidly; a fresh vivid red, often slightly bleeding granular tissue developed, at times with granulations so luxurious that cauterisation with lapis was expedient. Of late I have often applied this method. No caustic was applied, however, to the above-mentioned patients, for it was important to make the tests as far as possible exclusively with incitamin. Wherever ulcers were attended with pain, the latter ceased after a short time; this fact is greatly in favour of the preparation. In one case of ulcus cruris one remedy after the other had in turn to be given up owing to the pain it caused; treatment with incitamin was carried out with no difficulty, and the ulcer healed. Even in the case of X ray and radium ulcerations—where pain is most intense and persistent and, as a rule, can only be relieved through the employment of strong narcotics—the preparation did not fail. In Case 5, an X ray ulcer, the patient was under the necessity of sprinkling the ulcer with anæsthetics to sustain the pain. As soon as dressing with incitamin was employed the pain diminished considerably, and ceased entirely a few weeks later. The same thing happened with other patients with similar ulcerations.

Properties and Indications.

Incitamin is no panacea; like every other remedy it has its limitations, but the lines of these cannot be indicated with any degree of certainty on the basis of the comparatively slight material—about 50 cases—at present at my disposal. The estimation of the importance of a vulnerary remedy is no easy matter; the number of these remedies is legion, and if particular interest attaches to a new remedy, it must necessarily accomplish more than those previously employed. The recorded instances make indisputable the various qualities of incitamin; not least important of them is its soothing power, which induces the patients gladly to acquiesce in its employment. In cancerous sores its effect

Importation of Sodium Salts.

Mr. NEWBOULD asked the President of the Board of Trade whether he was aware that six small samples of sodium salts, sent on the 5th instant from Paris to a firm in London for test purposes, were being detained by the Customs authorities; that, on the 11th instant, the Customs authorities advised the consignee that the samples were being detained in order that entry should be made, value declared, and duty paid: that the consignee replied on the same day that the samples together weighed less than 1 lb., were of no commercial value, and were not dutiable; and that he wrote again on the 18th instant complaining that the samples were still detained; and whether he would have inquiries made into this case.—Mr. HILTON YOUNG (Financial Secretary to the Treasury) replied: I am having inquiries made and will inform the hon. Member of the result in due course.

Housing Schemes.

Mr. NEWBOULD asked Sir John Gilmour, as representing the First Commissioner of Works, whether he could make a statement as to the number of housing schemes on which the Office was still engaged and the number which had been completed.—Sir JOHN GILMOUR replied: The Department is engaged on 47 schemes for 32 local authorities. Four schemes have been completed.

Suggested Repeal of the Insurance Act.

Sir EDWARD NICHOLL asked the Minister of Health whether, in view of the dissatisfaction with the working of the National Insurance Act, he would consider the advisability of its early removal from the statute book.—Sir A. MOND replied: I am aware that there is periodical criticism of certain aspects of the scheme embodied in the National Health Insurance Acts, but on the whole all the evidence tends to show that national health insurance has been most beneficial in its operation. While I am considering the advisability of inquiring what improvements may be effected in its working there can be no question of repeal.

Insurance Act Contributions and Expenses.

Mr. HAYWARD asked the Minister of Health what were the total contributions of the State, employers, and employed, respectively, under the National Health Insurance Acts for the last complete financial year; and what were the total administrative and working expenses under all heads for the same period apart from payments made in respect of medical attendance, drugs, and other benefits.—Sir A. MOND replied: The totals (in round figures) for the year 1920 as respects England and Wales are as follows:—Total contributions by State, £8,800,000; by employers, £9,800,000; by employed, £10,300,000. Total administrative and working expenses under all heads, £1,500,000.

Medical Examination of Aerodrome Workers.

Mr. MYERS asked the Secretary of State for Air whether he was aware that in connexion with work at the Shotwick Aerodrome for a permanent depot for the Air Force the workmen were being subjected to medical examination although the employment was only of a temporary character; that several men over 50 years of age had been discharged in consequence; that one man had been discharged for having three defective teeth; that this action was causing resentment amongst the workmen and might involve a stoppage; and whether he would give instructions that all men employed on work of a temporary character should not be subjected to medical examination of this kind.—Capt. GUEST replied: The regulations provide that civilian employees (unless casually employed for less than six working days) will, on engagement, be examined by a medical officer as to their physical fitness for employment. A rigid standard of physical fitness is not, however, required, and it is sufficient for the medical officer to ensure that prospective employees are—(*a*) fit to carry out the work for which they are engaged; and (*b*) not suffering from any infectious or contagious disease. I am calling for a report in the case referred to, and will communicate with the hon. Member.

Expenditure on Public Assistance.

Sir WILLIAM DAVISON asked the Chancellor of the Exchequer what was the total national expenditure from both rates and taxes on public assistance in 1910 and 1920 respectively, especially under any Acts relating to the Poor-law, education, provision of meals, old age pensions, public health, housing, national health insurance, unemployment insurance, &c.—Mr. HILTON YOUNG replied: The hon. Member will find all the information available set out in a recent return of the total expenditure under certain Acts of Parliament, House of Commons Paper 139 of 1921.

Post Office Medical Appointments.

Sir WALTER DE FRECE asked the Postmaster-General whether he would undertake in future to give preference to all candidates applying for the post of Post Office medical officer who served in the war, even if their absence from home in the service of the State naturally gave them a shorter record of home service in the district.—Mr. F. G. KELLAWAY replied: Service with the forces during the war is regarded by the Post Office as a very important factor when appointing medical officers. But to regard it as the only factor of importance would be detrimental to the medical service. The fact of a doctor being absent from his district during his service with the forces would not be allowed to prejudice his prospects of obtaining a Post Office appointment.

TUESDAY, OCT. 25TH.

Venereal Disease and Divorce.

Mr. RENDALL asked the Secretary of State for the Home Department whether, as the giving of venereal disease by a husband to a wife, or vice versa, could not be made the subject of an action for damages or the sole ground of an application for a separation or a divorce, the Government would propose legislation to amend the law in these respects.—Mr. SHORTT replied: I regret that I cannot hold out any hope of legislation on this subject at present.

Employed Contributors and Health Insurance.

Mr. ALFRED DAVIES asked the Minister of Health whether he had received any protests from approved societies with regard to the circular issued to them allowing to treat employed contributors under the National Health Insurance Act with a certain amount of latitude in the event of the necessary number of contributions not having been paid in consequence of unemployment; whether he was aware that the circular was regarded as inadequate and that certain approved societies were urging the reintroduction of the benevolent fund or the deduction of a percentage of each society's valuation surplus to be placed in a separate fund, so that the liability might be distributed over the whole of the societies and not limited to any particular one whose members had been hardest hit by unemployment: and whether he would give this matter further consideration.—Sir ALFRED MOND replied: It has been represented to me by approved societies of various types that the concession recently made with reference to the arrears of insured persons who were employed for less than 26 weeks in the past contribution year is not sufficient to meet the needs of the case, and the whole question is having my careful consideration with a view to the immediate introduction of amending legislation.

Appointments.

KIRK, JOHN, M.A., B.Sc., M.B., Ch.B.Glasg., D.O.Oxon., has been appointed Honorary Assistant Ophthalmic Surgeon to the Royal Eye and Ear Hospital, Bradford.

THOMAS, W. E., L.R.C.P. & S.Edin., L.R.F.P.S.Glasg., Medical Officer of Health for Bridgend, Glamorganshire.

TURTON, J. R. H., M.B., B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the Royal Sussex County Hospital, Brighton.

WATKYN-THOMAS, F., B.Ch. Cantab., F.R.C.S. Eng., Assistant Surgeon to the Central London Throat and Ear Hospital.

Bradford Municipal Hospital (St. Luke's).—Senior Physician, WILLIAM WRANGHAM, O.B.E., M.D.Lond.; Junior Physician, W. H. THOMPSON, M.R.C.S.Eng; Senior Surgeon, BASIL HUGHES, D.S.O., F.R.C.S.Eng; Junior Surgeon, COLIN MACKENZIE, O.B.E., F.R.C.S.Eng; Ophthalmologist, G. H. OLIVER, M.R.C.S., D.O.Oxf.; Anæsthetist, W. E. HAYBURN, M.B.Camb.

St. Mary's Hospital Medical School Medical Unit.—LANGMEAD, F., M.D., F.R.C.P.Lond., Director; WILSON, C. M., M.D., B.S., F.R.C.P.Lond., First Assistant; ALPORT, C., M.D., M.R.C.P.Lond., Second Assistant; CALVERT, E. G. B., M.D., D.P.H.Belf., Third Assistant.

Certifying Surgeons under the Factory and Workshop Acts.—MILNE, J. M., L.R.C.P. & S.Edin., L.R.F.P.S.Glasg. (Carnoustie); REYNOLDS, W. A., M.B., Ch.B.Bristol (Paignton); and MCTURK, J., L.R.C.P. & S.Edin., L.R.F.P.S.Glasg. (Newton Stewart).

Vacancies.

rapidly to the attack of the fungus as to starve it showed what was called hyper-sensitiveness. What happened was not known; no toxins or antitoxins had been shown to exist, symbiosis appearing to be a delicate balance between physiological processes of the host and the parasite. Where the host plant carried the disease there was a condition somewhat similar to the case of carriers in human disease.

One of the striking things about plant as compared with animal diseases was the absence of known cases of acquired immunity, and, as a result, of true cure. In plant disease no substances had been detected corresponding to antitoxins, bacteriolysins, and so forth, nor was there any evidence of chemical warfare between plant and infecting organism. The cells of the host plant once entered nearly always died; the plant, therefore, resisted disease by keeping the invader out. In man one of the common results of disease was a bodily reaction associated with high temperature and evidence of general poisoning. In plants there was no general reaction; plants were attacked locally and each cell or group of cells fought a lonely battle. As the result of local attack, and the absence of a central reservoir, it was naturally difficult to isolate toxic substances. It had been suggested that botanists might get some help from vaccine and serum therapy, but, apart from the lack of evidence as to the production in plants of immune bodies, no satisfactory means existed of introducing sera or vaccines, there being no blood stream to distribute them. A fundamental difficulty often overlooked was the manner of growth. The plant continuously produced new organs; hence, to be effective, acquired immunity would have to be transmitted to what really was a new generation of the plant.

An Ultra-Microscopic Organism.

A class of disease known as "mosaic" had come to the front in the last few years; it was characterised by alternate patches of light and dark green coloration on the leaves. Known for a long time in plants like tobacco, this disease was highly infectious, although no infecting organism had been observed. In this respect it might be compared with yellow fever or measles. There were many theories as to the origin of the disease, but Prof. Blackman himself believed it to be due to an enzyme, the virus being destroyed by alcohol and other antiseptics as well as by heat. As with yellow fever, mosaic disease was largely carried by insects—namely, aphides. One of the best known cases of symbiosis was that known as *Mycorrhiza*, which actually penetrated and lived inside the cells of roots. Although the host plant controlled the development of the fungus, yet without its presence in the soil the plant did not develop satisfactorily. In one group there was a compulsory association between the fungus and the higher plant; in the case of ling (*Calluna vulgaris*) the seed even would not develop properly without the presence of the fungus. The fungus exhibited the phenomenon of attenuation when cultivated by itself; in symbiosis something occurred like phagocytosis, as hyphæ underwent digestion inside the cells. Stimulus to development, however, took place long before digestion began, and the higher plants could keep the fungus away from the growing points. A Japanese orchid had become so dependent on an invading organism that it had ceased to produce roots and depended absolutely upon the fungus for its water and food. A unique case was that of darnel (*Lolium temulentum*), the fungus being present when the embryo developed, passing through the integument into the interior of the embryo, from which it never emerged.

In conclusion, said Prof. Blackman, in spite of a number of definite points in which plant disease showed resemblance to animal disease, the similarities were less than the dissimilarities. Comparative pathology in the case of plant and animal diseases was still in its infancy.

SMITH'S PHYSICIANS' AND SURGEONS' VISITING LIST.

We have received from Messrs. Hazell, Watson and Viney, Ld., of Long Acre, London, a copy of Smith's Physicians' and Surgeons' Visiting List, which is now in its seventy-sixth year, and is presumably well known to many of our readers. This pocket-book is prefaced by an almanack, and by the usual contents of all almanacks, such as postal regulations, the monthly and weekly value of annual incomes from £1 to £1000, directions for making a will, tables showing the expectation of life, weights and measures, &c. For a more specially medical public suggested scales are given for professional fees, a table of eruptive fevers, and other tables showing average heights and weights of man, and the proper dosage for drugs in proportion to the age of patients. There are also lists of the principal poisons and their antidotes, an elaborate prescribers' compendium, an abstract of the Infectious Disease Notification Act, and a list of benevolent societies having the medical profession as their object.

A large portion of the pocket-book is naturally taken up with a journal ruled for ordinary visits and for obstetric and vaccination engagements, with spaces in which to keep cash accounts. Vacant pages are left for lists of drugs and instruments wanted, and (quite an important matter) for things lent. We have nothing but praise for a handy and comprehensive pocket-book.

X RAY APPARATUS.

We have received from Messrs. Schall and Son a new edition of their catalogue descriptive of the X ray apparatus which they are prepared to supply to the medical profession, and it is accompanied by a note upon X rays in gynæcology and in the treatment of malignant diseases. This interesting note gives a fair summary of the good results which have been reached at the Universities of Erlangen and Freiburg in the treatment of some diseases of women and some deep-seated malignant diseases by X rays, while the catalogue contains full description of the apparatus for the production of rays of suitable power for deep radiotherapy.

BRIGHTON WATER-SUPPLY.

For the first time for 30 years or more the Brighton corporation has been obliged to give only an intermittent supply of water. Street watering disappeared long since, but still the daily consumption in the district showed no diminution, averaging, in fact, 40 gallons per day per head of the population. This the authorities consider represents a considerable waste, and with a shortage of water in the wells the corporation has felt bound to curtail the supply. This is now being done by shutting off the water from the mains daily from 5 P.M. to 5 A.M. The Brighton water-supply is obtained from chalk wells on the South Downs.

THE REAPPEARANCE OF OSCAR GRAY.

To the Editor of The Lancet.

Sir,—The disappearance of a Rugby schoolboy was described in a letter to The Lancet of Oct. 15th, which gave reasons for supposing that it might have been due to temporary mental conditions consequent upon a fall, which, in fact, had immediately preceded it. The boy's absence must have caused acute distress to his relatives, as there have been other disappearances, recently chronicled in the press, for which no solution has ever been found, and which may have had a fatal ending through foul play or otherwise.

Oscar Gray has, however, been found, enlisted as a private in the Royal Engineers. An interview with him in the *Daily Express* assigns military ambition and a desire to earn his living at once as his motives, and records him as saying with reference to the search made for him that it was "very amusing." One of his observations was, "I never wrote to my people, I kept on putting it off. I suppose I had not the imagination to realise how they would be worrying about me." If this boy is a typical schoolboy his performance is a curious revelation of boyish psychology. Lack of imagination may have played its part, but it was combined with a lack of consideration for others which, it is to be hoped, is not characteristic of the younger generation. He appears to have found no difficulty in enlisting under an assumed name, and presumably without any inquiry as to his identity or character. This at his age is a circumstance which seems to require explanation.

I am, Sir, yours faithfully,

Oct. 23rd, 1921. A Parent.

Irish Births and Deaths.—For the second quarter of the present year the birth-rate for Leinster was 23·7, Munster 19·3, Ulster 24·1, and Connaught 18·0—the figures being per 1000 of the population according to the census of 1911. During the same period the death-rate was 15·9, 14·9, 10 1, and 14·5 for the four provinces taken in the same order.

CONVALESCENT CARE FOR ARMY NURSES.—A Red Cross holiday hostel for nurses and V.A.D. members is to be opened at St. Helena's, Folkestone, on Nov. 1st. The hostel will be staffed by V.A.D. members recently returned from France, and the warden is an ex-Army matron. Guests will remain for a month, or longer if necessary, the prices charged being reasonable. There is a compassionate fund at the Red Cross headquarters, from which grants can be made to cover visits to convalescent homes and for supplementary treatment.

Notes, Short Comments, and Answers to Correspondents.

INCITAMIN:

A NEW REMEDY FOR THE TREATMENT OF SLOWLY HEALING SORES.

BY PROF. J. F. FISCHER,
DIRECTOR-GENERAL AT THE MUNICIPAL RONTGEN CLINICS OF COPENHAGEN.

ON the introduction of the antiseptic method, when the primary healing of ulcers became the rule, the administration of ulcer remedies had to be considerably limited, and they were likewise to a great extent modified and simplified. There are, however, many ulcers which, owing to their situation and nature, cannot be treated antiseptically, and, notwithstanding the very considerable progress made in local treatment, we still have to contend with ulcers which only heal with difficulty and to which one treatment after another is applied in vain.

During many years' work as an X ray therapeutist, I have been sometimes confronted with the task of having to treat deep, gangrenous, very painful, necrosed ulcers with a minimal healing tendency, the chronic course of which is the despair of both patient and physician. When treating such ulcerations, where nutrition of tissue is exceedingly slight and the regenerative power almost lost, every generally applied remedy is tried in turn; if the necrosis is deep-rooted, the treatment will, as a rule, prove useless, but continuous treatment lasting years may now and then lead to a satisfactory result, or the object may possibly be attained through an operation.

A patient who had on the back of his hand an ulcerous cancer slightly larger than a penny (the only possible form of operation being an amputation) was first treated with radium, and thereafter with X rays. Though the growth proved only very slightly radio-sensitive, and the radiotherapeutic result could not consequently be very encouraging, treatment was nevertheless continued for a rather long period, at the earnest request of the patient. The consequence of the prolonged treatment finally became apparent, the irradiated part being transformed into a deep, fœtid ulceration, with necrosis of the sinews and denudation of the osseous tissue at the bottom. This deep ulceration was found to be considerably larger than the original tumour, and the question of amputation was no less remote than before. During my attempts to heal this ulcer—which presented a problem apparently insoluble—I had ample opportunity of studying the effect of the various methods, and in this case I first used a preparation made up on the basis of previous experiences. To this preparation, gradually altered in composition, I later gave the name of "incitamin," as I consider its main effect to be founded chiefly on an incitation of the sound tissue.

Results Gained by Use of Incitamin.

The application of this remedy produced a most surprising result; the necrosed tissue sloughed away, the fœtid odour disappeared, and in the course of some months the ulcer healed, except in two bean-sized places at the bottom of which were found partly relaxed sequestra. In this state the ulcer remained unaltered for a long time. The sequestra, displaying no tendency to slough, were removed by an operation, and the microscopic examination proved that they contained cancerous tissue.

Highly encouraged by this case—where, contrary to my expectations, a healing of the sore had occurred, except in the places where the malignant tissue had not yet been destroyed—I have during the last eight or nine months made use of the preparation on other ulcers of a more or less chronic nature. Altogether I have had the opportunity of completing the treatment of about fifty patients. Space will only permit me to record some few of these cases, and only the essentials of each case have here been noted. The preparation is referred to in the reports as "Fischer's fluid."

CASE 1.—M. G., female, aged 42, unmarried; X ray, late ulceration. Treated from March to June, 1919, for fibromyoma uteri. Received during the three months on each skin area 15 Holzknecht units, beneath 4 mm. aluminium filter. Three seances. Distance 28 cm. In November of the same year the skin on the right side of the abdomen became much infiltrated and red; here a very painful and progressively deepening ulceration was formed. There was no irritation in any part of the irradiated skin. Was treated with ordinary remedies without success, the pain continuing the same. In March, 1920, the ulcer had the extent of a hen's egg, with infiltrated, undermined edges, and in this case be preferred to a gift of facile teaching; if both cannot be had. The Unit may not teach much directly to the undergraduate, but it will form his teachers and "create an atmosphere." Those of us who had not such advantages—at any rate not at home—found out to our shame that on the old individual system it took us a quarter of a century to learn how to teach the beginner. And, as Dr. Wilson admirably says, in the Unit there is something more than the craft teaching—"nothing is so important (to the students) as the mute example of the lives of their teachers. . . . . that they should have in their midst a body of men whose lives are given to something other than the lucrative rewards of private practice."

And as for the Director, so for his associates; the settled work of the unit brings many blessings with it—not least a relief for a while from care and fuss, from hustling advertising methods, and anxious pressure towards premature publication. The organised worker has time to read and, what is better, to think, to assimilate new knowledge in meditation and converse, to sweeten his mind in familiarity also with art and letters; on the other hand, he has not to grudge the time for the prosecution of the more tedious and elaborate methods which make for thoroughness. If we fail to secure Directors having these ideals and qualities, the great expense of their institution will, as Dr. Wilson says, be wasted. Such a waste is to be deprecated at any time, at this time it is perilous to the whole movement. No risks must be run while parsimony is to begin, not in the fortresses of material ascendency, but upon the finer issues of the human spirit—in education, in health, in the finer arts, about which the public is supposed to be less vigilant.

ELECTION OF DIRECTORS.

The difficulty of securing Directors such as we desire suggests a few remarks on the mode of their election. It is easy now, when good appointments have been made in the London University, to say, nevertheless, that the mode leaves something to be desired. At present the election is virtually in the hands of the honorary staff of the hospital concerned. It is true that hitherto the hospital staffs have used their power loyally and with moderation; but this gives us no guarantee for the future. In the London University it would be better for the Senate to establish standing election committees, renewed by rotation, of independent—that is, ad hoc unofficial—persons of distinction in the several parts of Medicine. The hospital staff would thus be relieved of the duty not only to consider the claims of particular interests or promotions, but also those of past services or private friendships.

On the distribution of the teaching of the hospital I venture to formulate some definite principles. We are not to suppose that, in medicine, surgery, or gynæcology, to establish the Unit is to disestablish, or even to diminish, the teaching of the rest of the honorary staff. In my view of this matter the teaching of the undergraduate would remain almost wholly with the honorary and resident staff, as in the past; though the several parts and methods of it should be distributed and organised in some close dependance upon the Unit. Advanced instruction in the specialist departments would be in intimate association with the Unit. Do we not foresee two kinds or varieties of teaching, each to be distributed to its own quarters? The undergraduate knows that his time is short, and examinations near ahead; he wants his instruction to be precise, terse, and dogmatic; he is not ready for twilight apprehensions, nor for tentative and balanced judgments, nor for adventures on the outskirts of the known. He is apt to call them "rot." What he wants he will get better from the less speculative and more empirical side of the house. As I have said, our English teaching is for the prentice stage excellent, perhaps incomparable: do not let us disturb it. The director of the more advanced work, the team-work, will gather about him rather the pioneer squadron, the graduates who need "refresher" courses, men who have gained time and self-control enough to let loose a little imagination; he will attract the foreign visitors, and draw to his side—let us hope—some of his own honorary colleagues. Bence-Jones's frequent introduction of eminent foreign professors is among my happiest and most fruitful recollections of St. George's. Such an audience, such disciples, will be numerous enough to make the Directors' classes as large as they ought to be. And besides these there will always be borderers, half-ripe students moving between the junior and senior sides, who will blend the teaching into a whole, and diffuse the "creative atmosphere," the breath of the spirit on the face of the waters. If I may allude to my own experience, the Directors will do wisely to make place incidentally for their brother directors of pathological and biochemical laboratories to address the classes on special or more knotty points of their several subjects. Thus the senior student is led to recall his half-forgotten drills and discarded text-books on physics and chemistry, to realise the unity of all these sciences, to discover in their search the omnipresence and omnipotence of surface actions, of ions, of catalysis, of colloid and other molecular chemistry, and so forth. Thus they learn also that to look forward they must continually look backward and beneath. Nevertheless each unit should be provided with its own small laboratory for current work; the larger or more continuous work being consigned to the central laboratories. Indeed, the unit laboratory will be rather differently schemed and more specifically furnished. It can hardly be said as yet to exist in English hospitals, and abroad it is often too far from the wards. One general feature of the unit teaching however there must be which I would not overlook—one of wider appeal. The Director in each clinical department should be expected to give a clinical lecture—say once a week—in the chief theatre, generally with a patient before him; lectures which should be open free to all and any hearers, lay or medical (many biologists, &c., are not doctors), who may choose to attend. Such lectures should be milestones on the pathways of hospital research, and, as they would need careful and leisurely preparation, one public lecture a week in term from each director is all that should be required. I would urge also that, if possible, *a pupil of any one Unit should be made free of all Units*, London and provincial.

THE OUT-PATIENT DEPARTMENT.

Now let me touch upon—I need do no more, as Dr. Wilson has made mention of it—a cardinal feature in the new system—namely, a radical reform of the Out-Patient Department. The changes needed, and the main lines of them, are, I think, so well recognised that I need not stay to dwell on them. But in view of these changes let us not, as Dr. Wilson warns us, overload the Directors with beds. The Director ought not to be burdened with routine, and the out-patient work, with its "beginnings of disease," will occupy much of his attention. One might suggest 40 beds, male and female, as sufficient if, by the courtesy of his colleagues, he is offered some selection from the other beds in the house. By their aid he would be enabled to group cases along special lines of research. The intention is, I hope and believe, especially in the out-patient rooms, to invite outside practitioners to make use of the hospital for consultations in necessitous cases; and further perhaps, under some system of payments, for opportunities of hospital resources, such as X ray work, cardiography, blood culture and morphology, metabolic rates, biochemistry, and so on for patients in less narrow circumstances. In these days of insurance, when almost everyone has his doctor, an office notice should be sent of every in-patient reception to the family practitioner, with a statement of the hours of attendance of the consulting staff and an invitation to attend if he wishes to do so. The wish would grow. We do not realise the waste and mischief of dismissing a patient after (say) eight weeks or more of elaborate investigation and treatment, often indeed has naturally been temporary, although as an anodyne and cleansing agent it has not been without effect. In strongly suppurating ulcers incitamin is not particularly indicated, its domain being pre-eminently the torpid, stagnant ulcerations. In syphilitic and tuberculous sores the remedy does not produce any great effect. But in ulcera cruris incitamin has, on the whole, proved very satisfactory. The recorded cases prove that ulcers of long standing, uninfluenced by all other methods, have been healed with comparative rapidity through treatment with incitamin. With regard to tibial sores, the aim is to have them healed while the patients are yet in motion. If they heal during confinement to bed, the risk of relapse when the patient gets up is very great; ulcers treated with incitamin may be more secure against relapse than those healed in another way, but the healing is not fully reliable. Confinement to bed cannot, as a rule, be avoided at the beginning of treatment, but when the size of the sore has obviously diminished—i.e., when the growth of fresh epidermis is progressing—the patient should get up for increasingly long periods every time, in order to proceed to ambulatory treatment as soon as possible. I have sometimes carried a successful treatment through outside hospital by means of home nursing.

At the beginning of this article I mentioned that my interest in the question of a vulnerary remedy which would effect to a higher degree than those hitherto employed, the generation of tissue, arose through my dealings with ulcers which both as regards pain and healing tendency proved intractable within a reasonable period. The usual inorganic preparations and vegetable infusions (the latter in several cases proving superior to the former) proved, on the whole, to be of so little use that I experimented with other preparations, and ended by treating these ulcers exclusively with animal-organic substances. As appears from the above, my work in this direction has not been without success.

Composition of Incitamin.

My attention has chiefly been directed towards extract of the pancreas, pepsin with its tissue-conserving qualities, saliva—which so far as animals are concerned plays a part in the healing of sores—and towards serum. I shall not enter more closely into my numerous experiments—some satisfactory, others futile—the result of my researches is the organic preparation, usually referred to as Fischer's fluid, to which I have now given the name "incitamin."

This preparation is composed of horse serum treated with trypsin and freed from coagulable substances, horse saliva, and carbolic acid. The composition is about to be altered, and I cannot at present give it more exactly. The preparation is now produced under my personal supervision, and may be obtained from Serpens, Ltd., Christianiagade 16, Copenhagen.

Incitamin is a colourless or slightly yellowish, not quite clear fluid; after standing for some time it deposits a sediment, but is not thereby rendered less useful. The durability of the preparation has been tested by keeping it for a considerable time in a thermo-state, but it is always safer to keep it in a cool and dark place. It is non-poisonous when the method of producing it prescribed by me is followed; this fact is sufficiently demonstrated by the extensive controlled use made of it. In the preparation of incitamin certain precautions must be strictly observed; and for this reason every bottle will therefore be provided with a control number which guarantees that the preparation has been tested by injection into mice and guinea-pigs, and in other ways. Incitamin is administered in the form of poultices in such a way that a thick, well-wrung gauze-compress, a little larger than the sore itself, is placed on the sore and covered with a waterproof substance, preferably gutta-percha paper, the whole being kept in place by a dressing. The dressing is changed every morning and evening, but more frequently if there is much suppuration or any pain. Any cavity in the ulcer must be filled up with gauze, moistened with the preparation. As a rule incitamin does not irritate the skin surrounding the sore; even if—as often occurs with ulcus cruris—the skin is atrophic, there may be a beneficial effect. Any irritation of the skin may be treated with an ointment, but the latter must not reach the edges of the sore. Incitamin is counter-indicated where idiosyncrasy for carbolic acid is present; but carbolic acid is only present in ½ per cent.—and in none of those treated by myself have I found idiosyncrasy.

For assistance rendered me in preparation of the remedy my thanks are due to Mr. Marcussen, chemist. I must also thank the senior physicians who have permitted trial of the remedy in their wards, especially Dr. P. N. Hansen, chief surgeon, and Dr. H. Bing, senior physician, who has in many ways rendered me valuable assistance.

Rescue Work in S. Africa.—Dr. L. G. Irvine's book on First Aid and Rescue Work in Mining, reviewed in THE LANCET of Oct. 8th, may be obtained in London from the Technical Bookshop, Salisbury House, London, E.C. 2.

COMPARATIVE PLANT PATHOLOGY.

IN his Chadwick Lecture on Plant Diseases and their Relation to Diseases in Man, delivered before a large audience in the lecture room of the old Chelsea Physic Garden on Oct. 20th, Dr. V. H. Blackman, F.R.S., professor of plant physiology and pathology in the Imperial College of Science, attractively set out the resemblances and differences between disease in the animal and the vegetable organism. There was, he said, great variety in the degree of anatomical association between host and parasite. Sometimes the actual parasite merely lived on the surface of the leaves or other parts of the plant, any injury being mainly indirect, either by blocking the pores or by obstructing light. There was a closer association when the surface parasite by means of suckers took nourishment from the host. A more intimate degree was shown by the parasite which actually lived within the plant. The main part of the fungus might live in the intercellular spaces, putting out suckers to absorb the nourishment of the living cells; or the parasite might live wholly inside the cells. Some of these conditions were illustrated on the screen by microscopic sections of *Plasmodiophora brassicæ* (club root), which attacks turnips, kohlrabi, and other cruciferous plants, causing tuber-like swellings.

Physiological Association.

Plant disease, the lecturer went on, was simply abnormal physiology, and the most promising line of investigation involved the question of physiological association. Some associations could hardly be called parasitical—when, for instance, the invading organism lived on the products of death, or when two organisms lived together to their mutual advantage. He would take two cases from the extreme ends of diseases as shown in plants. When a plant was attacked by grey mould (*Botrytis cinerea*) the threads of the fungus penetrated the tissue of the host in all directions and brought about the death of the plant tissues. The cells of the host were reduced to a mere mush, the killing action being due to secretion by the hyphæ of an enzyme which dissolved the cell walls. It was not necessary for the cells to be penetrated as the hyphæ could kill at a considerable distance; the fungus really lived on dead tissue and was therefore hardly a parasite at all. How did it get into the tissues, to do which it was necessary to penetrate the cuticle covering the leaves which acted as a barrier against invading organisms? The fungus had either to force the barrier or turn it. The spore of *Botrytis* threw out a tube surrounded by a gelatinous layer, with the help of which the tube attached itself to the leaf and forced its way through the cuticle. It was not till the tube had got through, that chemical action occurred and the cells were killed; the cuticle prevented any action by the enzymes. The physiological relations of *Botrytis* were thus very simple; it mechanically forced its way into the plant, when the enzyme which it secreted killed the cells and the fungus lived on the dead matter. An example more physiologically complex was afforded by the rust fungi (*Puccinia*), the highest group of true parasites. They had no gelatinous sheath and a totally different method of penetrating the tissue of the host. They did not force the barrier, they turned it. The spores sent out germ tubes along the leaves of the host until they found a stoma which was entered, whereupon the hyphæ came in contact with the cells and abstracted nourishment from them. So far from the cells being killed they were stimulated by the presence of the fungus and proliferation of the tissue followed. This presented one of the great difficulties in studying plant disease, for symbiosis often developed. In the present case the fungus was the dominant partner. After a time certain changes took place in the cells; they became disorganised and died, and the symbiosis passed into a condition of true parasitism. Knowledge was needed of the process which led to harmony at the beginning and later on to disharmony.

Defence Against Disease.

What defence had the plant against such diseases as these? The *Botrytis* forced the barrier, but if the cuticle was resistant enough a fungus could not get in. In some cases the chemical nature of the cell wall was such that the plant could not be attacked. The cuticle also played another part. The fungus cells could not penetrate unless supplied with nutriment, and the supply was related to the degree in which the cuticle allowed the diffusion of substances out of the leaf. This was illustrated on the screen by slides showing that germination of spores on glass produced very short hyphæ, on a rose petal they were longer, and on a cactus longest of all, since the cactus supplied the most food.

In discussing the defences of higher plants against disease, the lecturer said that many forms of *Puccinia* attacked cereals and different wheats showed varying degrees of immunity. Almost any rust fungus could enter almost any leaf, but unless the plant was susceptible the fungus did not inoculate the leaf. Tissues which succumbed so and deeper study; a difference which is perhaps coming about, more or less undesignedly. In any case the universities must not trifle with their standards. At the Congress of Universities at Oxford, on July 8th, 1921, Prof. Joly dwelt on the educational value of even elementary research. He said: "I believe the outlook of a student who has carried out one single research of an elementary kind is different from that of one whose outlook is derived solely from the text-book and the examination. He learns first hand the mental point of view of the investigator. He gets ideas of scientific truth, and of the legion of errors which lie in wait around it, as may in no other way be acquired. He sees the plausible prima facie conclusion break down under the control experiment, or in the light of the inexorable requirements of other participating laws of nature." This lesson we learn in Cambridge from our M.B. and M.D. theses; the student who has done no more than work up an M.B. thesis has awakened in himself a new faculty; he is a new man.

WHOLE-TIME AND PART-TIME.

One point of Dr. Wilson's article only remains: Is the director of a Unit to be a "whole-time man" or a "part-time man"? It may seem that with the growth of a reputation outside the hospital the temptation to strain a permission to accept outside calls would become irresistible. Again, it is said that the public have some claim on a physician or surgeon of exceptional skill; and furthermore that some outside experience gives the professor a wider view of life, and makes for gentleness and humanity. These last qualities surely have a rich soil for growth in the hospital itself. From my knowledge of foreign clinics, where the professoriate is generally on unit lines, I believe that usually some outside consultations are permitted; yet I am assured, on good authority in many cities, that no misunderstandings arise. The outside fees are pitched high, the professor has work enough to make him indisposed to add largely to it, and he gains moreover an affection for his clinic and a love for research which tend to keep him at home.

Finally however we shall abide by Dr. Wilson's counsel to go slowly, learning our way as we go; that we may develop a system, not in facile imitation of other countries and conditions, but in harmony with the needs and temperament of our own people.

PS.—The important memorandum presented to the University Grants Committee by Sir Wilmot Herringham and Sir Walter Fletcher on their return from the United States in May, 1921, came into my hands after this article had gone to press. All I can now do is to desire for it universal attention; and not in our profession only. It is an encouragement to find that the opinions and counsels of the authors are in close accord with my own.

THE FIRST

Mitchell Lecture

ON

TUBERCULOSIS:

ITS RELATIONS TO GENERAL BODILY CONDITIONS AND TO OTHER DISEASES.

Delivered on Nov. 1st, 1921, before the Royal College of Physicians, London,

BY F. PARKES WEBER, M.A., M.D., F.R.C.P.,
PHYSICIAN TO THE GERMAN HOSPITAL, LONDON; FORMERLY PHYSICIAN TO THE MOUNT VERNON HOSPITAL FOR CHEST DISEASES.

PRESENT POSITION OF TUBERCULOSIS PROBLEM.

MY lecture consists mainly in explanatory remarks on some of the main points of the modern tuberculosis problem, illustrated by the relations of the disease to other diseases and general conditions of the body.

The results of clinical observation and experimental research seem to show that tuberculosis, which Sir Robert Philip terms "a vicious by-product of an incomplete and ill-formed civilisation," is—if all "carriers" of tubercle bacilli and all cases of latent tuberculosis be included—so widely spread in the civilised communities of the world that it would be far more reasonable to try to segregate those individuals who have escaped infection than those who have been infected.[1] On the other hand, amongst civilised communities the mortality from tuberculosis seems to be gradually diminishing, apparently as a result of: (1) Relative immunity to "massive" infection, due to infection during early life with minor forms of the disease; (2) diminished frequency of "massive" infection—a result of the modern application of hygienic preventive measures; (3) increase of the general standard of health—less poverty, less overcrowding, less overwork, better food, and better air.

In civilised communities infection (according to the results of von Pirquet's cuti-reaction and similar tests) chiefly takes place during childhood, the occurrence of congenital tuberculosis being so rare (see further on) that it is practically negligible. Apparently the initial infection generally escapes attention, and the disease is at once more or less effectually resisted by the natural vital processes of reaction in the body so that it remains permanently latent, the tubercle bacilli becoming quiescent or gradually dying out altogether. Obviously, all state or national anti-tuberculosis schemes should include special attention to the welfare of children (especially the children of the poorer classes): (1) by furthering their general health; (2) by diminishing the chances of "massive" and frequently recurring infection—for example, by removing them (as is done by the French "Œuvre Grancher") from parents and others suffering from "open" tuberculosis; and (3) by methodically looking out for the first signs of infection and by employing the best means to oppose the disease directly that the first signs of infection are discovered. The tendency to suffer from severe or fatal tuberculosis probably varies somewhat according to inheritance (families and races)—that is to say, owing to a process of Darwinian survival of the fittest amongst communities which have been long exposed to tuberculous infection (Karl Pearson, &c.). Doubtless, the chief reason why the disease especially often tends to assume a grave, rapidly progressive and fatal form in members of primitive communities is that they have hitherto escaped infection (owing to want of exposure) and in their resulting unprotected condition have, on their coming to live in towns or coming in contact with cases of open tuberculosis, been exposed to "massive" infection, just as unprotected children are exposed to "massive" and recurring infection by close contact with tuberculous parents, nurses, &c. (suffering from active and "open" tuberculosis).

Routes of Entry of the Tubercle Bacillus.

The most important routes by which tubercle bacilli gain admission to the body are by inhalation through the air-passages and by the alimentary canal. I may mention here that the placental route (congenital tuberculosis) is so rare that in 1916 I was able to collect practically all the known examples (published in various countries) into a short article on the subject.[2] It is doubtful whether infection ever takes place from man to woman by the genital route. The bacilli very seldom enter the body by way of, or through, the skin, but infection by this route has probably occasionally occurred, for instance, in connexion with the operation of circumcision, by chance wounds, or by direct cutaneous inoculation in various ways. In patients with lupus vulgaris or "scrofulodermatous" lesions, who likewise suffer from tuberculosis of the lungs or other internal parts, the infection with tubercle bacilli has almost certainly been much more often carried from the internal parts to the skin than from the skin to the internal parts.

Some Comments
ON
CLINICAL UNITS.

BY THE RT. HON. SIR CLIFFORD ALLBUTT,
P.C., M.D., F.R.S.,
REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

IN the issue of THE LANCET for July 2nd of this year (p. 33) Dr. C. M. Wilson, of St. Mary's Hospital, published certain reflections of weight and importance on this subject. I have been invited to make some comments on Dr. Wilson's article, and to express a further opinion upon this new system—new in England—of medical teaching and research. Dr. Wilson's article is so far-sighted and even-handed, so well balanced between the ideal and the practical, that if I may venture to comment upon it, and to underline it, I can add nothing. How then for the best is the new system to be constructed, and to be used for these ends? We all agree that, in advanced work, teaching, if it is to be effectual, must be inspired by research; and, to most researches at any rate, teaching, if not too elementary or too laborious, is one of the incitements.

Some years ago, in the pre-war period, Sir William Osler wrote to ask me to take part in an endeavour to attract to English schools some of those overseas students who then were betaking themselves to Paris, Berlin, or Vienna; but hardly deigned to visit our medical schools, even on their way. With these aspirations I agreed, warmly agreed; but argued that these visitors would come here when there was something definite to come for, and not till then. In those continental capitals, as also in the New World, Medicine was taken seriously both as science and art; as seriously, let us say, as astronomy, engineering, chemistry, agriculture, and so forth. In these and other vocations, to teaching and research highly qualified men were giving their lives. In like manner, in the foreign cities, scientific medicine was in the hands, and under the influence, of a professoriate. Yet the visitor to a great London hospital school would then have found some admirable elementary teaching for junior classes it is true; but that for the eminent men of the staffs, men whose names were household words, the hospital visit was but a part, indeed a secondary part, of their calling. As things were, the main time and available energy of these masters of their craft were spent, and necessarily spent, not in the medical school but in Harley-street. Their hospital teaching was but a scattering of crumbs from their tables. In a short hour or two the visitor would pick up some impressive and sagacious remarks; aphorisms worthy of Hippocrates; thoughts distilled out of a large empirical experience and great personal qualities; but to leisurely and systematic clinical research, to patient devotion in clinical investigation, there was hardly a pretence. Nor was any one member of a hospital staff made personally responsible for the coördination of the clinical studies. Osler's brief reply was characteristic of him: "I am showing your letter to X., Y., and Z.; it will do them good." I need not occupy space in saying how, under one influence and another, a revolution is now coming about in certain large hospitals; a professoriate has been founded in their schools, and systematic progress is being made.

PRACTICAL *v.* THEORETICAL.

There is an old and perhaps perennial schism between the "practical man" and the "man of theory"; indeed, the word "theory" has become almost a term of abuse. Each has some right on his side, and the "practical man" is well aware of the right on his own. But in our time the development of the physical sciences has become an essential condition of congregation in large cities, as essential as was magic in the welding of primitive folk; and as under this urgency the strides they have made have been enormous, the contrast has become more and more vivid; the theoretical man is regarded as a child in affairs, the practical man as a "muddler through." Thus in our profession the practical, that is the clinical, man declares that he has little use for the laboratory, while the scientific physician is apt to regard the clinician as a mere empiric. Yet, if there are truths and values on both sides, we must try so to blend these opposites that each may enlighten and reinforce the other.

For it is true that if the two methods are not radically different they are somewhat divergent. The scientist, seeking for a "shorthand" expression of a series, must proceed by selecting those features of things which they have in common, and by neglecting those which are individual. He empties out the peculiar features which to the clinical man are precious. To the scientist values are irrelevant, the clinical man thinks that it is only in *being* that one thing is better than another; the scientist delights in the width of his comprehension of things, the clinical man tries to penetrate into the innermost recesses of the personality, and finds it to be no less inexhaustible. Moreover the practical man complains that the scientist encourages the student to evade the discipline of particular diagnosis by instrumental short cuts. Happily however the majority of physicians are neither mere scientists nor mere clinicians, but partake of the qualities of both characters. The ideal therefore that we have to aim at is so to educate the student—graduate or undergraduate—that he shall not be a scientist detached from individual instances, but, whatsoever his calling, a practitioner; a practitioner however whose clinical observation and invaluable traditional rules of thumb shall be enlarged and corrected by the breadth, the methods and the accuracy of analytic science. How is this end to be attained? To answer this question Sir George Newman and the Clinical Units are addressing themselves, and Dr. Wilson is examining their position and prospects.

COMPOSITION OF A CLINICAL UNIT.

In any field of science and practice a small school must depend on the chances of individual leaders; but for the growth and advance of a large school the "spearhead" must be forged of more permanent and more various materials. The leader must not be superseded; he must become the foreman of a team. Such a combination is called the "Unit"; and the members of it are in union to fortify, inspirit, and supplement each other in the search for and discovery of knowledge. This function, if less directly engaged in the teaching of students, yet makes for the life and increase of the whole school. In Medicine there has been, indeed, a great waste of workers. Young graduates of ability, attracted by the life and movement of the school, and unwilling to pass away at once into the somewhat superficial routine of practice, too often, during the most precious years of their lives, have been left to hover about the field while they ought to have been in the thick of the battle. These men are now to be welded into the spearhead, and will do brave work; helping on the cause, and training and storing their own minds before settling down to more material engagements.

But who are to be the leaders? I am tempted to go so far as to say that, if possible, a school should not construct, or renew, its unit until it sees, within or without its own walls, the man it needs. It must have the foresight to discover its new leader among the young men, say under 40 years of age; the leader should not be a mere clinician, nor merely a laboratory worker, but one who has a "footing in both camps," and knows the scope and power of each. He should produce evidence of work, not merely diligent and incidental, but systematic, consistent, coherent, and imaginative; work showing both grasp of detail and breadth of view; and above all he must have in him the fire to kindle other men. These qualities should peritoneal tubercles. In the same way a temporary tuberculous bacillæmia may lead to the development of single or multiple tuberculous foci in various parts of the body—lungs, bones, urogenital organs, choroid tunic of the eye, &c.—which may or may not ultimately (directly or indirectly) give rise to grave trouble. A minute subpleural tuberculous focus, arising in the same way, may become quiescent or obsolete, and yet (as I shall further on endeavour to explain) subsequently give rise to an attack of pneumothorax.

INFLUENCE OF OTHER DISEASES ON TUBERCULOSIS.

Besides the general conditions of nutrition and specific immunity already referred to as favouring or opposing tuberculosis, the latter disease may be influenced by other diseases. I discussed the evidence on this subject in 1901, in a paper on the "Relations of Tuberculosis to other Diseases,"[7] and since that time I have, of course, observed other illustrative cases and have collected many additional references on the subject, which, however, I cannot fully enter into here.

Diabetes; Syphilis, &c.

The condition of the blood in diabetes mellitus, when there is hyperglycæmia, has been supposed to favour the growth of tubercle bacilli,[8] and the emaciation due to the severer forms of the disease has been supposed to lower the general resistance of the body towards tuberculosis and some other infections. But the severer forms of diabetes mellitus occur especially at youthful ages, when grave pulmonary tuberculosis is likewise rather frequent, and the less severe forms of diabetes mellitus in older persons seem to be by no means specially associated with tuberculosis. The wasting due to diabetes insipidus has been similarly supposed to favour pulmonary tuberculosis, but in certain cases the diabetes insipidus itself has seemed to be caused by tuberculosis in some way affecting the posterior lobe of the pituitary gland.[9] Syphilis, by producing a condition of cachexia, is said to favour tuberculosis, but syphilis is often unaccompanied by any cachexia, and I am by no means satisfied that it always increases the gravity of tuberculosis when both diseases are present together. True syphilitic cachexia is, I think, relatively rarely seen nowadays. It is, indeed, astonishing to note how generally "well-nourished" old syphilitics often appear. Septic counter-infections apparently favour the re-awakening and dissemination of old tuberculous foci, as traumatism[10] (contusions, &c.) may also do. I am inclined to think that the presence of old quiescent tuberculous pulmonary lesions of moderate degree does not greatly increase the gravity of attacks of pneumonia and the pulmonary complications of epidemic influenza, if the influenzal infection does not re-activate the tuberculous lesions. There is a general idea that alcoholism diminishes the resistance of the body towards tuberculosis. Broken-down alcoholics furnish favourable soil for the extension and dissemination of tuberculosis within the body, but doubtless the effect of alcoholism in regard to tuberculosis is largely an indirect one—connected with neglect of (or want of) general hygienic conditions, poverty, &c. Unfortunately, the young children of alcoholics may be adversely affected by the same indirect influences, and become thus likewise predisposed towards tuberculosis, because of their alcoholic parentage.

Hepatic Cirrhosis.

The relation of tuberculosis to hepatic cirrhosis in human beings has been the theme of many clinical and pathological reports; and investigations—chiefly experimental—in animals have been undertaken to elucidate the subject, a subject which was concisely summed up by Sir H. D. Rolleston in 1912.[11] The published literature would fill a large volume, but an elaborate analysis of it was made in 1914 by S. Schönberg,[12] who also contributed some original work of his own. It is probable that tuberculosis, as well as many toxic conditions, especially those directly and indirectly due to alcoholism, favour the development of cirrhosis of the liver. But various forms of hepatic cirrhosis, with or without jaundice,[13] may be a direct result of a chronic tuberculous process within the liver itself, associated with tuberculosis in the territory of the portal circulation or elsewhere in the body. For the development of cirrhotic changes a local vital conservative reaction is, of course, necessary. When the liver is unusually deficient in resistant power, obvious macroscopic caseous changes may occur, and, as is well known, in terminal cases of miliary tuberculous dissemination it is usual to find tubercles present on microscopical examination of the liver. A tuberculous cirrhosis may result when the tissues are very resistant towards the tubercle bacilli, or when the latter are few in number or of low virulence.[14] In connexion with tuberculosis a terminal toxæmic jaundice with hepatic atrophy occurs in rare cases.[15]

This subject is connected with that of the rôle of alcohol in the production of hepatic cirrhosis. Chloroform and various other toxins have been proved, by experiments on animals and by accidental occurrences in human subjects, to injure the liver so as, in "massive doses," to give rise to acute or subacute necrotic parenchymatous changes—and probably, under certain circumstances, to bring about chronic cirrhotic changes—for instance, if administered in smaller repeated doses (that is to say, when chronic reactionary processes are set up in the tissues). Undoubtedly, alcohol is one of those toxins which can injure the liver (though probably its injurious effects vary in different individuals), but its direct rôle in the production of cirrhosis has been over-estimated. Cirrhosis of the liver may arise, altogether independently of alcohol, from various known and unknown causes. On the other hand, alcoholism probably tends to diminish the resistance of the hepatic tissue (as if it dulled the sensitiveness of the cells and lowered the rapidity of their reaction) towards various pathogenic microbes, including tubercle bacilli, and enables the microbes to remain alive in the liver and thus (when not virulent enough to cause extensive cell-necrosis), to set up chronic reactionary inflammatory and sclerotic changes. Alcoholism is now becoming much less frequent in most parts of the world, and the effect of this circumstance on the frequency and types of hepatic cirrhosis will furnish an interesting and important field for future observation and investigation. As the rôle of alcohol becomes less and less, the other factors in the causation of cirrhosis will probably become more manifest.

Hodgkin's Disease; Heart Disease, &c.

In spite of the view that Hodgkin's disease (lymphogranulomatosis maligna) is intimately—and perhaps causally—allied to tuberculosis, I do not think the obtainable clinical and pathological evidence and the ordinary experience of hospital physicians point to much real relationship between the two diseases. The two diseases may certainly be both present together, because Hodgkin's disease often shows itself in early adult life when grave pulmonary tuberculosis is common. Neither do I think that there are any special relations between tuberculosis on the one hand and the various forms of carcinomata and sarcomata on the other, though carcinomata most commonly occur in persons beyond the period of life at which grave tuberculosis is most frequent. In regard to heart disease everyone must admit that pulmonary tuberculosis in an active stage is very seldom found (clinically or by post-mortem examination) in persons with mitral valve disease and chronic passive hyperæmia of the lungs,[16] but the supposition that patients with congenital pulmonary stenosis who reach the age of puberty mostly die from pulmonary tuberculosis is probably incorrect. In former times the latter patients were doubtless often kept, as many chronic invalids, under unhygienic conditions (in insufficiently ventilated rooms, &c.), specially favouring the onset of pulmonary tuberculosis. At present they not rarely die from super-added malignant endocarditis. In connexion with this subject it must not be forgotten that heart disease in rare cases is due to an active cardiac tuberculosis.[17]

Gout; Renal Disorders.

Active pulmonary tuberculosis is seldom found in gouty subjects or associated with true granular kidney, though at post-mortem examination in such cases fibrotic patches in the lungs may point to a active tuberculous disease having been formerly of grave or crucial operation, and then leaving the home doctor in the dark to pick up the broken threads as he can. Moreover, with his aid the "following up" of patients will be made easier and more perpetual.

On the medical side I am strongly of opinion that insanities, at any rate in their manageable phases, should be included with other maladies in the ward and out-patient services, even if only for example's sake. The methods of convenience which exclude and segregate these diseases probably have a bad effect on the sufferers themselves, but they are infinitely more noxious in implanting and nursing the notion that "mental" disease is not bodily disease but something over, under, or beside it. What would be the misfortune to pathology if, let us say, diseases of the kidney were swept out of sight of general medicine? All bodily functions are interdependent; yet again, in tuberculosis, syphilis, and some other infections, such divorces are at least foreshadowed, and should be distrusted.

GRADUATE TEACHING.

On the arrangements for graduate teaching I must make some brief remarks. Of the efforts made to this end by the Royal Society of Medicine and by individuals we cannot speak too gratefully. But, as in my correspondence with Sir William Osler, I drew back a little until the unit system should be settled and in action; for it seemed to me that the two movements must hang closely together. Before the Earl of Athlone's committee I demurred to, and indeed deprecated, the costly proposal of setting apart a peculiar hospital for this part of advanced instruction. Graduate teaching, if not confined to the units, must surely be sown, rooted, and watered in them. A central office and club for these graduates is desirable, but to separate their hospital study would cut the graduate off from the main streams of medical ideals, organisations, and activities; would deprive the units of their senior disciples, and compel the aspiring graduate, whose time is limited, either to desert the peculiar hospital or to surrender the privilege of attending the courses, and of coming under the influence, of one or more of the half a dozen most eminent leaders of the day in medicine and surgery, men of whose friendly encouragement he would have retained a happy memory for the rest of his days. As to the graduates who need only a "brush up," surely there are already in the great hospitals many competent teachers, and hundreds of beds, awaiting their arrival. We are agreed that the choice of leaders is strait; these men are few, and these few are needed for the units; and as the senior men on the honorary staffs are not likely to desert their posts, so the staff of a hospital peculiar to graduates would fall into the second rank. But, after all, of the irony of the world we have many instances, and is there one more mordant than this—that whatsoever we may do to develop and furnish the mind and enlarge the experience of the general practitioner, and to display to him what *can* be done, we send him away (unless he happens to practise near a university town) whither he will find none of these modern means for the application of his new knowledge. Is it not kinder to keep his eyes closed, and his mind in ignorance, that his soul may be at peace?

PROPORTION IN MEDICAL EDUCATION.

And these problems of education lead us on to other difficulties, which the units will have to work out. In his interesting and plain-spoken Hunterian Oration of 1921[1] Sir Charters Symonds declares that in our zeal we are piling up the weight and number of subjects of medical instruction beyond all toleration. To lighten the burden Sir Charters Symonds proposes a utilitarian reform or rather retrogression; he advocates what, rightly or wrongly, is virtually a return to apprenticeship. The student is to be brought to the bedside at the outset, in order that he may have before him continually the aptitudes for which he is to work. Anatomy is to be pruned, and a good third of it cut out, by rejections of its academic features (p. 12). Physiology is to be domesticated in like manner, but not so drastically. The peculiar discipline of anatomy as a standard of close observation and accuracy might thus be lost, for this discipline is all or nothing. Sir Charters Symonds (p. 15) "by no means wishes to be understood as decrying the study of the collateral sciences—these 'handmaids' of medicine"—(but) "do they hold, as taught to-day, their due proportion to the later subjects? However well informed a man may be in the preliminary sciences, the final court of appeal is at the bedside." He must attend rather to the cry of the children than to physical apparatus. And (p. 16) "*The only opportunity the student has for independent observation, it seems to me, is in the clinical field, and the sooner he is brought there the better.*" (Italics in original.) This assertion seems a little hard on the present training in the "collateral" sciences. With one sentence at least we shall all hopefully agree—namely, that "one day we may see the physiologist at the bedside" (p.17). The pathologist should be a frequent, or indeed a regular, assessor.

Does not this discourse on the whole reflect the mind of the craftsman, and rightly so, but at the same time diminish the scientific and thinking physician and surgeon? More than once I have discussed this sort of scheme with engineers, both professorial and practical, and find, with them as with ourselves, that promising as a plan of early shop work may appear, the apparently irremediable consequence, in the ordinary student, is that at a later stage his attention to the science of his profession cannot be recovered; he settles down on rule of thumb, and is quite contented without its principles. The housemaid knows well enough how hot water may crack a glass vessel, but cares not why. But ere long the scope of the units will have to be reconsidered. I venture to repeat my oft-told opinion that the divorce of medicine and surgery, due to medieval disdain of handicrafts, cannot last. In this generation already it has landed us in an absurd position. Such specialism as must be will be on a plan, perhaps a topical plan, of redistribution, and the physician (to use the word in its general sense) must learn to deal, as does the gynæcologist, with all sides of his case. And are not these phrases "collateral" sciences, "handmaids of medicine," and the like, misleading? These sciences are not annexes of medicine, nor frills about it, but partake of its very nature; they are mothers, not hirelings. As Sir David Prain said the other day to the Pharmaceutical Society: "Originally, practical pupilage worked fairly well. The surgical *fabrica* . . . . was patent to the eye, and (aseptic principles being unknown) success in practice depended on caution, manipulative skill, ... natural capacity, and saving common-sense. But students discovered that they could not grasp (the underlying truths) . . . . without some kind of physics, and some understanding of the structure and function of vital mechanisms."

But it is true notwithstanding that the tides of teaching are overflowing the banks! What are we to do? We may indeed take parts of the past into the future, but we cannot walk backwards. At present we are asking what the Units will tell us. Sir Charters Symonds says that under the unit system the first year's men are being called into the out-patient department: a call that should come from all the recognised teachers. He says also that no one desires to lengthen the curriculum. This may not be our desire but it is what we are inevitably doing. At Cambridge we are putting back the physics and chemistry to the schools, and with some success; yet, even with this anticipation, university students are in their sixth-seventh year when they come up for graduation. It may be that professional preparation will divide into two courses—into a five-years course on craft lines for the diploma of the colleges, and a university course for those who have the turn and the time for wider within two months, but later the patient died suddenly from the effects of a dissecting aneurysm of the aorta. At the necropsy the lungs were found free from tubercles, but there were some dilated air-cells, *especially near the apex of the left lung*. Here, again, it must be remembered that emphysema-bullæ near the apex of the lung (especially in the young) are likely to be connected with a cicatricial tuberculous process. In short, it seems that most cases of "spontaneous pneumothorax arising in apparently healthy persons," and certain cases (rapidly spontaneously recovered from) arising in persons with clinically obvious tuberculosis, are late or accidental results of a cicatricial reaction to a local process. They are (rare) "accidents" directly connected with the normal healing process, by which most (if not all) of us in civilised communities have to resist the invasion of our bodies by tubercle bacilli. The prognosis in most cases is good, both in regard to the pneumothorax and in regard to the tuberculosis; for in most cases the tuberculosis has already been practically overcome by the time that the "accident" in question occurs.

---

[1] THE LANCET, Feb. 19th, 1921.

CONCLUSION.

I ought perhaps to apologise for having made the title of this lecture so widely inclusive. Indeed, the relation of tuberculosis to various general conditions of the body includes a consideration of the various clinical forms of tuberculosis in relation to the specific resistance of the body towards tubercle bacilli (both the human and bovine types), and, therefore, also the relations of pulmonary tuberculosis to lupus, tuberculosis of the lymphatic glands, &c.; the whole subject of "scrofulosis"; and also the relations of pulmonary tuberculosis to local disorders and "accidents" connected with the resistance of the tissues to local tuberculous foci. I have merely been able to sketch the subject in this lecture. I have practically not entered into the question of the relations of tuberculosis to the so-called cutaneous tuberculides and the various other skin diseases which have, by certain writers, thought to be (at all events, sometimes) ætiologically in some way connected with tuberculosis. In regard to the single subject of the relatively rare cases of spontaneous pneumothorax occurring in apparently healthy persons a volume could be filled by short descriptions and an analysis of the 200 cases or more that have already been published.

The general trend of my remarks may be summarised as follows:—

1. That one of the most important connecting links between tuberculosis, especially pulmonary tuberculosis, and various general conditions of the body and local diseases and "accidents" in various viscera, is the state of the patient resulting from the tuberculous infection itself, either through its toxins or through the local presence of tubercle bacilli, and through the local and general reactive processes by which the body more or less successfully opposes or overcomes the bacillary parasitic invasion.

2. That it is only with the help of such relative processes of resistance, which may be greatly favoured and encouraged by general and special antituberculosis hygiene, that the human race can hope eventually so far to gain the upper hand that tuberculosis may very largely lose its character as one of the most frequent causes of death and disability.

3. Occasional visceral and cutaneous diseases and "accidents," of which I have taken "spontaneous pneumothorax arising in apparently healthy persons"—though relatively rare—as a type (and have therefore dealt with it at slightly greater length than the others), should be regarded as tokens of the price which we may be called on to pay if our struggle against tuberculous infection is, on the whole, effectual.

References.

I have referred to very few authors out of the immense number whose work deals with the subjects of my lecture. I take it that many of the omitted names of authors are household words to medical men interested in the subject. My own writings which I have quoted can be consulted for some of the numerous references that I have failed to give here.

I may here give my personal experience of a cutaneous infection, though it was hardly likely to have been my first infection with tubercle bacilli. One early morning, about October, 1890, when house physician at the Brompton Hospital, I happened to get a slight punctured wound into the deeper cutis vera of the terminal segment of the right forefinger. This bled rather freely at the time, but I had forgotten its existence by the afternoon, when I handled a lung at the post-mortem examination on a virulent case of pulmonary tuberculosis. The slight wound on my finger nevertheless healed up, but afterwards there was troublesome itching and swelling, and, later on, intermittent painful swelling with more or less local redness; there was no actual formation of pus. The little swelling was kindly excised by Prof. von Eiselsberg in Vienna about January, 1891. He wrote to me that microscopical sections showed that it contained giant cells, but that no actual tubercle bacilli were found. The small operation wound healed up, but afterwards broke down again and discharged for some time, and then slowly healed up. During the winter 1907–1908, when examining patients at the Mount Vernon Hospital for Chest Diseases by the Wolff-Eisner-Calmette ophthalmo-reaction for tuberculosis,[4] I discovered that my own ophthalmo-reaction was more strongly positive than that of most or all of my patients who were tested in that way. In July, 1916, my Pirquet's cuti-reaction was an excessively strong one. Although, as I have said, the infection in 1890 is hardly likely to have been my initial infection with tubercle bacilli, an inoculation of that kind is, I think, interesting. It occurred just at the time when my general health and bodily vigour were at their maximum, and certainly my diet at the time was as antituberculous in quantity and quality as any diet could be (so indeed was that of all the house physicians at the Brompton Hospital at the time). It seems to me that in other cases chance infection with tubercle bacilli can seldom have occurred under circumstances more ideally favourable for the production of some degree of relative immunity.

According to Calmette, infection through the conjunctiva is possible in human beings—as by a crying baby's eyes being wiped with a handkerchief soiled with tuberculous sputum—and instillation experiments have proved that this port of entry may occur in animals. Calmette thinks that the usual initial site of entry of the bacilli in tuberculous subjects of all ages is the alimentary canal (including the mouth, tonsils, and pharynx) and holds that the bacilli may pass through a healthy mucous membrane without leaving any trace of their passage or noticeable disease in the nearest lymphatic glands—a process of infection not conforming to the so-called "Cohnheim's law." On these points, however, Calmette's views have not met with universal assent. The bovine type of tubercle bacillus, though relatively rare in ordinary chronic pulmonary tuberculosis of adult human beings, is now acknowledged to be by far the most common cause of tuberculosis of lymphatic glands in children. Calmette, however, points out that human tuberculosis is common in some countries where bovine tuberculosis is absent.

Problem of Immunity against Fresh Infection.

It is an important question how long persons who have successfully resisted tuberculous infection, and in whom all the invading tubercle bacilli have died out, retain any specific immunity towards fresh infections with living tubercle bacilli. Animal experiments suggest that this period is not long, and that successful specific preventive treatment, if any is possible, can be carried out only with cultures of living bacilli (in measured doses, and possibly attenuated) and not with any vaccine obtained from dead cultures.

The grave and fatal forms of pulmonary tuberculosis, occurring in young adults (and later on), which constitute the majority of cases of "consumption" seen in hospitals, are explained as due to dissemination (possibly during a period of temporarily lowered resistance) from a latent tuberculous focus left from an infection in childhood, or else as due to massive reinfection[5] in an enfeebled individual, or in an individual whose specific resistance to tuberculosis has been lowered as a result of all the tubercle bacilli from his initial infection in childhood having died out. The specific power of resistance to tuberculosis can certainly not be measured by the general state of the health. Analogously, during the last severe influenzal epidemic some strong and robust individuals rapidly succumbed to influenzal pneumonia, whereas, apparently weak and chronically diseased individuals, though similarly affected, recovered. It is well known that a strong healthy native of some primitive community, who has not been exposed to tuberculous infection, may fall a ready victim to the disease on coming into contact with tuberculosis in civilised centres of the world (cf. "Römer's law"). A vigorous man with a latent quiescent tuberculous focus may suffer from grave or fatal tuberculosis if massive dissemination occurs as a result of some chance contusion.[6]

The reason why the ordinary pathological-anatomical features of tuberculosis in adults of civilised communities differ from those most frequent in children and in natives of hitherto non-tuberculous regions of the world (on being brought to centres of civilisation) is now explained as being partly due to relative immunity and reactive power acquired by most persons through tuberculous infection in childhood. In this connexion one may note that there is probably some antagonistic relationship between ordinary lupus (or other relatively mild forms of tuberculosis) and grave pulmonary tuberculosis, in so far as patients suffering from ordinary lupus seldom fall victims to grave forms of pulmonary tuberculosis, unless they already suffer from the pulmonary disease before the lupus shows itself. In fact, patients with lupus generally appear to be resistant to the rapidly progressive forms of tuberculosis. When a patient has tuberculous infiltration in the upper part of the larynx, the tuberculous disease usually, I believe, proves fatal unless it is a case of lupus. This is quite in accord with the view that lupus is due to the bovine type of tubercle bacillus rather than to the human type.

In most cases, as previously mentioned, the initial tuberculous infection in childhood is doubtless overcome by the natural vital mechanism of resistance in the body, but tubercle bacilli probably generally remain alive for a long while, though latent and more or less encapsuled, in various parts of the body, for instance, in lymphatic glands. These bacilli are certainly not always effectually imprisoned, but may keep up a kind of guerilla warfare against their host by occasionally entering his blood-stream (temporary "tuberculous bacillæmia") from their fibrous fastnesses; and during such "raids" they may do serious or fatal mischief, for instance, by setting up tuberculous meningitis. Owing to such a condition of temporary tuberculous bacillæmia (which may be clinically supposed to be an "influenzal attack" or some passing febrile infection of unknown nature) an apparently non-tuberculous subject—in reality, a case of latent or "closed" tuberculosis—may disseminate tubercle bacilli in his secretions (Calmette), just as a tuberculous cow may secrete milk containing tubercle bacilli, even in the absence of any recognisable mammary tuberculosis, and (in animal experiments) tubercle bacilli may pass out in the bile without there being any obvious tuberculous lesion in the liver.

In this connexion I take it that temporary conditions of primary or secondary tuberculous bacillæmia (the "typho-bacillosis" of Landouzy, Léon Bernard, Armand-Delille, &c.) are much more common than is generally supposed—that these cases are often passed by as febrile attacks of unknown origin—that, though death may result owing to tuberculous meningitis, &c., the natural resistance of the body at the time is often sufficient to overcome the bacillary invasion—that in some cases the disseminated tubercle bacilli are able for a time to live and increase locally in various parts of the body, giving rise to attacks of miliary tuberculous pleurisy (including many cases of ordinary subacute and chronic pleurisy) and miliary tuberculous peritonitis, which are often more or less spontaneously recovered from. It is thus that attacks of tuberculous peritonitis would in many cases have been recovered from without having been recognised, had not a surgical operation for suspected disease of appendix or pelvic organs, or (as I have known) for the treatment of hernia, unexpectedly revealed the presence of metabolism, such as may be caused—possibly in common with other factors—by a vitamin deficiency in the diet.

The *modus operandi* in the case of the various vitamin deficiencies is still a matter of discussion. It has been suggested that there may be an aberrant metabolism of carbohydrate, in the absence of a particular vitamin. Alternatively, acidosis has been several times claimed to exist in connexion with deficiency disease, notably scurvy [12] and beri-beri.[13] I have been attracted by the somewhat picturesque suggestion of Dr. Eric Pritchard[14] that, in rickets, calcium ("available base") is withheld from developing bone, since it becomes more urgently required to neutralise acid products of incomplete oxidation. It is subsequently excreted in combination, and thus lost to the system. So also with magnesium and sodium of nervous and muscular tissues. I do not suggest that in rickets lime salts are actually dissolved out of bone, though indeed this must happen in osteomalacia, and perhaps also in adolescent rickets.

Probable Compensated Acidosis in Rickets.

The hydrogen-ion concentration of the blood has been shown to be normal in rickets, but the assumption is that a compensated acidosis is present, in that there is a lowering of the alkaline reserve of the organism. According to Haldane[15] the term used is a misleading one. The deviation from the normal in the hydrogen-ion concentration is actually too small to be observed by known physical and chemical methods. It can, however, be shown by the far more delicate method of observation of the accompanying changes in breathing, and in the excretion of acid or alkali and of ammonia by the kidneys.

In the case of rickets, the clinical findings previously referred to, as regards both excess feeding and the association of debilitating conditions with the histories of rachitic children, appear favourable to the existence of such a condition. Hyperpnœa, the obvious clinical manifestation of increased CO_2 output consequent on the presence of abnormal acid in the circulation, is certainly present in the acute crises of rickets. It occurs also in the spasmophilia and respiratory catarrhs associated with milder cases. The fact that such symptoms are entirely absent over intervening periods would point to the underlying condition being an intermittent or recurring one, of very varying intensity at different periods. This is borne out in the variations found from day to day in work on the calcium metabolism.

Dr. Engel[16] has recently chronicled cases of rickets in Germany, permanently dyspnœic, and dying with symptoms of acute air-hunger. There is, further, in rickets an increased urinary excretion of phosphates,[17] suggesting that an increased proportion of monosodium phosphate, relative to di-sodium phosphate, is being excreted for purposes of blood equilibrium. Dr. Pritchard's suggestion is further substantiated by the excretion of creatine in the urines of rachitic children.[18] This phenomenon has been shown by Underhill to occur in conditions of acidosis in absence of defect in carbohydrate metabolism.[19] Since creatine may be regarded as a substituted guanidine the recognition of guanidine as the toxin factor in tetany is of importance [20]; the injection of guanidine into rabbits with the production of tetany has been shown by Watanabe to be associated with acidosis.[21] Some degree of acidosis is without doubt present in both tetany and osteomalacia.[22] As regards blood-calcium depletion the condition in tetany would appear to be an exaggeration of the condition in rickets.[23]

A careful study of work on the calcium metabolism in rickets reveals nothing to negative Dr. Pritchard's view. The outstanding feature of the disease must be said to be an inability to use the calcium salts; the greater number of cases in my series developed rickets on a diet of cow's milk, containing a large excess of calcium compared with human milk. Unfortunately, it is impossible to distinguish between deficient absorption and true excretion in the calcium loss in the stools. There is no disturbance of fat metabolism; fat-splitting is adequate and normal.[24] Steinitz, Langstein and Meyer [25] identified fatty-acid excretions with loss of mineral constituents akin to the loss in rickets, with conditions of acidosis in young children suffering from gastro-intestinal disease, and showed an increased ammonia ratio in such cases.

Comparative Investigations into Urines.

With the object of deciding whether or no rachitic children were suffering from a lowering of their alkaline reserve (whether from the cause indicated by Pritchard or from some other cause) I decided, on the advice of Prof. W. Ramsden, to compare the urines of a series of rachitic children with those of normal children of the same age as to the proportion of nitrogen excreted as ammonia relative to total nitrogen excretion—and at the same time (or just subsequently) directly test their alkaline reserve, on the method of Sellard, Henderson and Palmore, by noting the amount of bicarbonate of soda dosage necessary to change the reaction of the urine (acid to alkaline).

The difficulties of the task I set myself were obvious; in the first place it was likely to be difficult to obtain urinary specimens from such young children, of the training and habits of the class indicated. Secondly, it was only possible to obtain such specimens in hospital, or some other available institution, where the main difficulty was to find an adequate number of children whom I could pass as sufficiently healthy to use as controls.

In all 65 children were investigated, comprising 30 rachitic children (healed, active, or recovering), 25 healthy children of the same class (controls), and 10 unhealthy children of the same class, not rachitic (further controls).

The children on the first list of controls (healthy children) were selected by me personally in two of the Liverpool Day Nurseries, to which I was admitted by kindness of Dr. Ruby McBirnie, infant welfare officer for the City of Liverpool. I was fortunate in securing almost complete 12-hourly specimens (the children went home at night) for my ammonia ratio estimations, in a majority of cases. In others it was only possible to take a mean of separate estimations on morning and evening specimens—as had to be done subsequently with the hospital children in a majority of cases. The rachitic children, with one or two exceptions, were in-patients at the Leasowe Hospital for Children (annexe for rickets and wasting babies), as also were the unhealthy controls. This second control list was undertaken for the purpose of ascertaining whether or no there was a distinction between this type of child and the rachitic child in the state of the alkaline reserve, the ammonia ratio being high in each case.

Method of Procedure.

The method of procedure with the bicarbonate of soda dosage was as follows: On the first day a normal afternoon specimen of urine was obtained and tested as to reaction to litmus (usually acid), titration acidity and ammonia content per 100 c.cm. On the second day gr. v. sodium bicarbonate was given three times between the hours of 9 A.M. and 3 P.M., and a specimen obtained for examination after 3 P.M., usually about tea time. If the reaction was still acid the dosage was increased to gr. x. three times on the third day, and, if necessary, to gr. xv. and gr. xx. respectively on the fourth and fifth days.

For charting purposes the children were subsequently graded as follows:—

Grade A Urine alkaline to litmus from the start.
" B " " " following gr. v.
" C " " " " gr. x.
" D " " " " gr. xv.
" E " " " " gr. xx.
" F Urine still acid, in spite of dosage.

All specimens were carefully preserved; a saturated solution of camphor in chloroform was used throughout for the purpose. Ammonia estimations were carried out by the Sorenson formalin method, immediately following receipts of specimens. For the nitrogen estimations the method chosen was Folin's micro method; this consists of a miniature Kjeldahl with present and having been successfully overcome. Many medical men have supposed that gout is antagonistic to, or retards, pulmonary tuberculosis,[18] and it seems that a genuine antagonism of the kind exists. In this connexion it may be remembered that according to life assurance inquiries, &c.,[19] "normal weights" and "over-weights" are less likely to die from tuberculosis than "under-weights," and so-called over-feeding probably in some cases both favours the development of gout and opposes pulmonary tuberculosis. However, the prognostic significance of "under-weight" in regard to the danger of developing active tuberculosis is much less in the second than in the first half of life. Under-weight may, moreover, sometimes be a chief clinical sign of the actual existence of, not merely of predisposition to, tuberculosis.[20] Equally complicated is the question of a relationship of pulmonary tuberculosis to habitually low brachial systolic blood pressure, relative cardiac hypoplasia, and the so-called "drop-heart" (as seen in Röntgen photographs of the thorax). Does the actual presence of the slighter forms of tuberculosis help to produce such conditions? [21] Albuminuria, chronic renal irritation, and actual chronic nephritis[22] may be due to the passage of tubercle bacilli and their toxins through the kidney. In some such cases, when there is great tissue resistance towards tuberculosis, miliary tubercles doubtless repeatedly develop in the kidneys and disappear again with or without giving rise to fibrotic changes.

I may mention here that W. H. Dickinson [23] (1875) found tuberculosis in 20·8 per cent. of 250 persons dying from granular degeneration of kidneys, which, according to statistics, was less than the average frequency of tuberculosis at all post-mortem examinations. I myself recorded (1892) that in a series of 145 necropsies on patients over 40 years old with pulmonary tuberculosis (nearly all of whom had actually died from their lung disease) there was evidence of some degree of chronic interstitial nephritis in 40 per cent., whereas, in a series of 44 necropsies on patients over 40 years old with healed or quiescent pulmonary tuberculosis 61·3 per cent. showed evidence of some kind of chronic interstitial nephritis.[24] Amongst the more recent writings on the connexion of chronic interstitial nephritis with tuberculosis those of S. Schönberg,[25] E. Kirch,[26] and O. Kieffer [27] may be especially mentioned. It seems that when tubercle bacilli are passing through the kidneys the resulting reaction and changes (if any) in the kidneys depend (much as the changes under analogous conditions in the liver) on the resistance of the tissues towards tuberculosis and on the number of tubercle bacilli and their degree of virulence. Typical tuberculous changes—macroscopic with caseation, or microscopic tubercles—may result when the tissue-resistance is low or the tubercle bacilli are relatively numerous or of high virulence; whereas cicatricial sclerotic changes (forms of interstitial nephritis) may occur, when the tissue-resistance is great or the tubercle bacilli are few or of low virulence.

In regard to all the above points I am sorry I cannot furnish any elaborate statistics of my own, and there is no time at my disposal in the present lecture to discuss them further. But I wish to explain that probably the most important of the conditions of the body related to tuberculosis are the conditions due to the actual tuberculous process itself—the results of the past fight of the body against the invading tubercle bacilli—especially the presence of encapsuled tuberculous foci and fibrous (cicatricial) areas in the lymphatic glands, the lungs, and elsewhere, pleural and peritoneal adhesions, and (most important of all) a general condition of resistance and partial immunity towards fresh tuberculous outbreaks and dissemination within the body and fresh tuberculous infections from without.

Tuberculides; Pleurisy; Pneumothorax.

Some of the results of these conditions may almost be dignified as "diseases"—for instance, some of the so-called cutaneous tuberculides (if they are really of tuberculous origin) and the renal troubles above alluded to as due to the presence of tuberculosis. Other results may be termed "accidents"—for instance, intestinal obstruction due to adhesions or stenoses resulting from past or chronic tuberculous processes in the mesenteric glands, peritoneum, or abdominal viscera. Modern observations show that very frequently attacks of pleurisy are due to miliary pleural tubercles and that very often the resistance of the body is sufficient to produce a cure. As "accidents" of the kind above referred to I would include nearly all cases of co-called spontaneous or "idiopathic" pneumothorax arising in the apparently healthy.

I first observed a case of this kind in 1899, and the literature on the subject is quite extensive.[28] At least 60 or 70 such cases had been published up to 1903, and since then many cases have been described from time to time in the medical journals by writers, most of whom apparently regarded the condition as one of extreme rarity. The pneumothorax in such cases may arise absolutely spontaneously or there may be some exciting cause such as laughing, coughing, or sneezing. The abnormal physical signs generally disappeared spontaneously within four or five weeks from their onset. In most of these cases I believe that the pneumothorax was due to localised emphysematous changes associated with localised quiescent or healed pulmonary tuberculosis—for instance, to the tearing of a superficial (subserous) bulla, perhaps connected by an adhesion with the opposite (parietal) pleural surface. (I believe that some of the cases of spontaneous pneumothorax, arising in clinically obvious cases of tuberculosis, but rapidly recovered from without liquid effusion or active interference, are due to a similar cause.) H. B. Whitney [29] recorded a case of pneumothorax occurring suddenly in a man, aged 70 years, who was supposed to have suffered formerly from pulmonary tuberculosis. On account of severe pressure symptoms the pneumothorax was tapped and a cannula was left in the chest for several days. Complete recovery followed. A superficial emphysematous change or a pleuritic adhesion, associated with chronic or obsolete tuberculous lesions, afforded the most reasonable explanation for the occurrence of pneumothorax in such a case. In support of this view Dittrich's case might be abduced.[30] It was that of a medical man, aged 28 years, who had quiescent pulmonary tuberculosis. Whilst walking he was suddenly seized with fatal left-sided pneumothorax, which the post-mortem examination showed to be caused by rupture of a subpleural emphysema-bulla situated in a portion of the lung (apex) showing cicatricial changes. It was long ago pointed out by A. Brünnicke, of Copenhagen,[31] that emphysematous changes might in certain cases be regarded as a connecting link between tuberculous lesions and pneumothorax; and it is noteworthy that in some such cases, in which pneumothorax has appeared to be due to the rupture of an emphysema-bulla, the emphysematous change has been found, not in the lower part of the lung—its favourite site in cases of ordinary pulmonary emphysema—but in the upper part, at or near the apex, in which position it is often associated with obsolete or quiescent tuberculous lesions. Thus, in a case of fatal hæmo-pneumothorax, described by G. Newton Pitt,[32] the cause was apparently the rupture of an emphysema-bulla near the apex of the right lung, but the bulla was adherent to the chest wall, and it seems to me that the existence of both adhesion and bulla in this case may very likely have been due to a former minute tuberculous lesion. Examples of pneumothorax due to the tearing of a superficial (subpleural) bulla fastened by an adhesion to the opposite (parietal) pleural surface are to be found in F. W. Zahn's paper of 1891.[33] In this connexion W. H. Ranking's case[34] may likewise be referred to, though it has often been quoted in support of a different view. It was that of a young man, aged 19 years, who, while at church, was suddenly seized with the symptoms of left-sided pneumothorax. The pneumothorax was gradually recovered from had very definite spasmophilia. G. M. on one occasion at least was seen in tetany. All were cases of uncomplicated rickets with the exception of A. H. (impetigo), A. S. (adenoids), and P. L. (otorrhœa). The majority at one year had no teeth, and were quite unable to raise themselves or to sit up. Most of the children were comparatively recent admissions to hospital. In view of the findings of Frew[26] concerning acetone in a series of cases at the Great Ormond-street Hospital, none of them were investigated during their first week.

Three points have to be considered in a comparison with controls: 1. The ammonia ratio—high in all cases—an average of 14·3 compared to 6·2 in the control list. 2. The condition of the alkaline reserve—reduced—out of 12 children tested, six were grade F, four of these were investigated the second week after their admission to hospital, and may be reckoned "untreated"; the fifth child, W. N., had been in hospital one month; the sixth, G. M., had suffered from tetany. The children graded C and D were either rather older children or cases of a less severe type. 3. The ammonia content (grammes per 100 c.cm.) is less constantly reduced following bicarbonate dosage. This suggests that a high ammonia formation was an essential of the metabolism present, even when additional alkali was supplied.

Recovering Cases.

These were a series of 14 children, slightly older than the active cases, with flabby musculature, bony deformities, and other general stigmata of rickets, usually well-developed. The majority had the more or less typical thoracico-abdominal deformity. They had been in-patients of the hospital for very varying periods—from 14 days up to one year. I believed the condition to be improving in all cases. The ammonia ratio remains high—average 13·2—though not quite so high as in active cases. The alkaline reserve is well established, in some cases above the normal. The urines of five of the children were alkaline on first examination—an alkalosis may be said to be present in these cases. Finally, it occurred to me that a comparison of three children admitted on the same day, two of uncomplicated marasmus, and one of active rickets, might be of interest. The children, of approximately the same age and weight (about half the normal at one year), were: T. W. (marasmus) 10 months, weight 10 lb. 9 oz.; L. M. (marasmus) 14 months, weight 11 lb. 12 oz.; M. H. (rickets) one year, weight 11 lb. 6 oz.

Clinically there was absolute distinction between the case of rickets and those of marasmus. The latter had good, white, well-formed teeth and hard bones; they sat up readily in bed, and could stand with assistance, T. W. at 10½ months. M. H., the rachitic child, had no teeth, and was quite unable to sit up at one year. Of the marasmic children, one—T. W.—had undoubtedly been simply starved. At the end of 14 days he had put on 2 lb., though still thin and miserable; appetite and digestion good and normal. The ammonia ratio in this case was high—17 per cent. The second case, L. M., was a more generally unhealthy child. In this case the ammonia ratio was 3·6 only. The children were together in Grade A of the alkaline reserve. The rachitic child showed acidosis; her reserve was Grade F. There was very little compensatory ammonia formation—ammonia ratio 8·6 per cent.

Remarks.

It is admittedly impossible to dogmatise on the metabolism in rickets from urinary work in a comparatively small number of cases. I do, however, claim that there is sufficient indication of a lowering of the alkali reserve in cases of active rickets for further work to be undertaken, more particularly work on the alveolar CO_2 content, when a satisfactory apparatus can be devised for use with children or from blood examinations, more particularly of the dissociations curve of hæmoglobin.

As regards the ammonia ratio in rickets, I believe this is a very variable quantity, according to the amount of reaction to the disease which is going on. In the most acute cases one finds a lowering of the alkaline reserve associated with a comparatively small ammonia ratio (cases Grade F in Table IV. show such a ratio, compared with other cases in the series). As the condition improves the ammonia content increases, and the alkaline reserve tends to resume the normal. Later the alkaline reserve will have become normal, and active disease is arrested, but the ammonia ratio is likely to remain above the average, so long as any tendency to acidosis persists. This is shown in the recovering cases. Ultimately in healed cases the alkaline reserve and the ammonia ratio are both normal.

It must be admitted that the relationship as to cause and effect between the condition shown and the disease is not clear. It is impossible within the limits of this paper to refer more fully to individual cases. One case I mention because I am quite unable to explain the phenomena present, even on the hypothesis of an acidosis, unless some specific toxic factor such as might give rise to an acute hæmolysis were present, possibly a specific acid. The child, M. C., aged 1 year, 11 months, included in my cases of recovering cases was a very ordinary typical case of rickets. From time to time she had run an intermittent temperature—on four separate occasions up to 103° or 104°—without general constitutional disturbance. The temperature was attributed to teething, which had been much delayed. No other abnormality was noted. After five months in hospital she became suddenly ill one afternoon, refused food and vomited. Her temperature ran up to 105°. She looked very ill and miserable, but nothing definite could be found wrong with her. The bowels had been opened freely that day, chest condition normal. Within 12 hours she became semi-comatose, high-pitched rhonchi developed in the chest, with rapid respiration and considerable dyspnœa. It was quite impossible to give food. There was no improvement under salines and stimulants. A few hours later I recognised acetone in the breath, but there was a very small quantity only present in the urine (catheter specimen). Typical post-mortem staining appeared in the skin, about the same time and at least six hours before the death of the child took place. There was a moderate amount of collapse, but I believe death was from asphyxia. I had never previously seen skin hæmorrhages of so marked and severe a character, except in very acute bacterial infections or in septicæmia. On post-mortem examination no cause of death was found; all organs appeared normal; the lungs showed no signs either of bronchitis or of broncho-pneumonia; the spleen was quite hard, normal colour, doubtfully enlarged. Blood cultures taken from the left ventricle of the heart were reported by Prof. J. M. Beattie (Liverpool City Laboratory) negative.

The only clinical condition which I have been able to find in any text-book at all resembling the conditions in this case is that described by Prof. Still, under the name of recurrent pyrexia. The cause is said to be an unidentified toxin, in Still's opinion, of intestinal origin. The hæmolysis in this case is interesting, in view of the blood picture in rickets. A secondary anæmia is usually described. Pritchard believes that the epiphysial enlargement is the result of the reaction of the blood-forming elements of the bone marrow to an active condition involving blood destruction.

It is obvious that new light thrown upon the metabolism in rickets is only valuable in so far as it may be utilised in the prophylaxis and treatment of the disease. In the present state of our knowledge the provision of easily digested and assimilable fat containing adequate vitamins (e.g., cod-liver oil) will remain popular. My own belief is that cod-liver oil is definitely serviceable when the diet has previously been deficient in fat, more especially if excess feeding is carefully guarded against by a careful regulation of the diet. Schloss has recently pointed out that there is no special efficacy in cod-liver oil alone, but good results are obtained by giving it in conjunction with calcium salts, presumably by a more efficient absorption of the latter.[27] This should apply to its addition

VITAMIN DEFICIENCY AND FACTORS IN METABOLISM

RELATIVE TO THE DEVELOPMENT OF RICKETS.

BY AMY HODGSON, M.D. LIVERP., D.P.H.,
ASSISTANT MEDICAL OFFICER OF HEALTH, HUDDERSFIELD.

I HAVE followed with keen interest recent controversy on the position of the fat-soluble vitamin as a factor in the causation of rickets. The work of Mellanby[1] has established that experimental rickets in puppies can be produced by a vitamin deficiency in the diet. Further, recent workers in America—McCollum, Simmonds, and Pitz[2]—have produced rickets experimentally in rats by diets deficient in other single factors—viz., low calcium content, poor quality of protein, and unsatisfactory salt combinations. Other workers emphasise the influence of confinement and laboratory conditions upon the health of the experimental animal.[3,4] This is not without importance in view of the opinion that confining conditions of modern civilisation, especially conditions in large towns, are at least predisposing factors in the development of the disease. There remains great enthusiasm in experimental circles for the deficiency theory of rickets; the theory is likely to become the more generally popular, outside those circles, because the step from the popular conception of a fat deficiency in rickets to the deficiency of a fat-soluble vitamin is an easy one. On the clinical side, interesting results have recently been published by Dr. Corrie Mann, Dr. Elsie Dalyell, and others.[5] It must be observed, however, that the work of Hess and Unger referred to by Hopkins [6] as a "clinical experiment," and perhaps the most valuable clinical contribution to date, is unfavourable to a vitamin theory of rickets.

It is now rather over one year since I began to keep exact records of cases of rickets in infant welfare clinics in the city of Liverpool, primarily with a view to checking and coördinating my own ideas on the subject. I will briefly state the results shown.

Results of Records of Cases in Infant Welfare Clinics.

Rickets occurs on every type of dietary, even on the breast alone, with no evidence that the natural supply is insufficient or unsatisfactory, and equally on an artificial diet of an entirely irreproachable character. One hundred and twenty cases were collected; of these 80 were breast-fed up to at least six months, 60 for a normal period (eight months to one year). The following table shows the occurrence of various foods in the dietary of rachitic children in this series when brought to the clinic:—

Cows' milk or modified cows' milk, including Corporation sterilised milk, 14	51
Full cream dried milks, Glaxo 22, Cow and Gate 1	23
Condensed milk (Nestlé's)	16
Neave's food	6
Allenburys' food	7
Savory and Moore's food	3

It is certain that war conditions and post-war prices, with the scarcity of animal fats, have extended the possibility of a vitamin deficiency, more particularly of the fat-soluble vitamin in the diets of a large section of the British public. I personally came to the conclusion that such a deficiency in the diet is not specially associated with rickets in a majority of cases. While certainly so associated in a proportion of the cases, it is equally a feature of the dietary of other children who do not suffer from rickets.*

While the character and chemical nature of the fat-soluble vitamin remain obscure or a matter of contention, and with its distribution as yet inadequately worked out, it is admittedly difficult to dogmatise as to its presence in or absence from dietary. Following the work of Hopkins and others,[7] rather than that of Drummond[8] recently published, I am assuming that the fat-soluble vitamin is relatively thermostabile. I have thought it safe to infer that this accessory factor is adequately present both in home-sterilised or pasteurised milk, and in the rapidly heated dried milks of the Just-Hatmäker or cylindrical process, but less generally so in the condensed variety of milk. In the case of slightly older children one may assume that a good supply of the factor is furnished by a diet containing butter, or cream, eggs, fresh country whole milk—especially if freely supplemented by such substances as virol or cod-liver oil. In the case of the breast-fed child the diet of the mother must contain a sufficiency of such substances and of green vegetables.

Consideration of Diets Received.

On these lines, I came to the conclusion that of 120 cases 64 had received a good supply of so-called anti-rachitic factor; of these, upwards of 30 had been taking virol or cod-liver oil sufficiently long for some degree of prophylaxis to be anticipated.[9] Twenty cases had definitely *not* received an adequate supply of vitamin. On the remaining 36 cases I found it impossible to arbitrate, the reason being that the source of the milk-supply in these cases was unknown. I must explain that a proportion of the Liverpool milk-supply is from fodder or meal-fed cows, kept in cow-sheds within the city. This milk, which is naturally fresher, is much sought after for infants as opposed to "railway milk." It is obviously deficient. As regards butter, owing to the generally persisting prejudice against margarine in the class to which these children belonged, many of the very poorest of them had received a ration of butter in their diet, whatever else they had gone without. Various faults in dietary were from time to time identified, but no constant common peculiarity between the cases could be established. There was, however, a history of abnormal appetite, accompanied by very definite over-feeding in a fair proportion of the cases. This is compatible with the opinion expressed by Hess and others—more commonly held in America than in this country—that rickets is apt to be associated with an *excess* rather than a *deficiency* in dietary. There would appear to be a relationship between the fulfilment of energy requirements—in which both dietary and hygiene are concerned as a law of supply and demand—and the development of rickets. A history of infection, with subsequent development or marked exaggeration of rachitic phenomena, was present in a much larger number of cases than I should have anticipated. Thus 36, out of 120 cases, had a history of infectious disease, often of one infection following on another, whereas other debilitating conditions, which may have been predisposing or contributory, were present in 32 cases, as follows:—

Measles	5	Gastro-intestinal conditions	14
Whooping-cough	5	Adenoids and otorrhœa ..	5
Chicken-pox	1	Infantile paralysis ..	2
Scarlet fever	2	Operations, harelip, and intussusception	2
Pneumonia	10	Tuberculosis, family history	3
Measles and whooping-cough	6	Furunculosis and eczema..	2
Measles and chicken-pox..	1	Scurvy	2
Measles, chicken-pox, and whooping-cough ..	4	Syphilis	1
Whooping-cough and influenza	1	Bright's disease	1
Whooping-cough and diphtheria	1		
Total ..	36	Total ..	32

I came finally to the conclusion that while errors of hygiene[10] and dietary and debilitating conditions generally were incidental, probably predisposing to the development of rickets, there must be some common determining factor still to be found, of which no obvious clinical or bacteriological evidence was in existence. It may be possible to trace some positive error in practice of massage the heart has been exposed by resecting the costal cartilages and opening the pericardium, but this method has been attended with a single success only. It is a somewhat severe operation, and the delay incurred is a serious disadvantage. The subdiaphragmatic mode of approach has nearly all the recorded successes to its credit, but I believe likewise a very large number of failures. It can rarely be entirely satisfactory. Bost and Neve[1] say that compression of the heart in this way is possible though difficult in the child, but in the adult it can rarely be effected, as only the cardiac apex can be reached, and this tends to slip upwards. Further they say that it is possible to obtain direct access to the heart inside the pericardium by an incision into the base of it from below the diaphragm; the left lobe of the liver and the stomach are, however, liable to get in the way in this operation; there is a risk of injuring the musculo-phrenic artery, and considerable difficulty in inserting sutures in the diaphragm and finally closing the incision. Bost and Neve[1] have therefore devised another method of obtaining direct access, which is briefly as follows: An abdominal incision is made, and through this the attachments of the diaphragm to the left costal margin are cut for 2 inches. The right hand is inserted into the left pleural cavity and the heart grasped outside the pericardium. During massage the parts are pressed around the right wrist to prevent air entering the pleural cavity. This method appears to me to satisfy most nearly the required conditions. Bost and Neve[1] obtained a success with it in a case in which the subdiaphragmatic method had previously failed, and Coleman[2] has recently narrated a somewhat similar experience.

---

* It is argued, of course, that if we assume an accessory factor responsible for growth, deficiency of which factor is responsible for rickets, a normal supply becomes a deficiency in the more rapidly growing children. This would be an adequate explanation of one of my cases—otherwise inexplicable except from the point of view of individual metabolism—a case occurring in one of twins who had been identically reared and fed. The better grown of the two was rachitic, the other was normal. The diet of these children had been unsuitable and inadequate, owing to extreme poverty, but not obviously deficient in fat-soluble A, as fresh country milk (1½ pints only daily between the two) had been furnished by the Liverpool Invalid Children's Association, and malt and oil supplied regularly to both children from the clinic

The Performance of Artificial Respiration.

Success as a result of cardiac massage is almost out of the question without artificial respiration, but there is abundant evidence that its performance has frequently been neglected. In man, judging by clinical records, as in cats, there is frequently a strong tendency to persistence of the respirations after primary cardiac failure, and no doubt cardiac massage, if performed soon enough, will assist to maintain them. Such efforts can, however, only be fitful and quite inefficient for the purpose in view as a general rule, although it would appear that recovery by massage has occurred in a few instances without artificial respiratory assistance. Artificial respiration by Sylvester's method is possibly sufficient when there is no opening into the pleural cavity, if it can be done without interference with the proper performance of massage. In an operation for direct access to the heart perflation of the lungs is without question the right method to adopt; it obviates the risk of the production of pneumothorax and provides for full inflation of the lungs when the hand is in the left pleural cavity. Intubation of the larynx can easily be performed on an individual in the flaccid condition following cardiac syncope, when the initial asphyxial spasm, if any, has passed off, and the lungs can be readily blown up through the tube by the lung power of another person. Perflation of the lungs by means of the apparatus employed for the intratracheal method of administering an anæsthetic should likewise be effective; a steady stream of oxygen passed direct from a cylinder through an intratracheal tube would serve exceedingly well, provided, of course, that the force of the blast is carefully controlled. A pair of bellows constitutes a simple apparatus for performing intermittent perflation. Even mouth-to-mouth perflation may be practised in an emergency, but one or other method must be employed in an efficient manner in conjunction with intrathoracic massage if cardiac massage is to be a practical success.

I agree with Gunn as to the importance of a proper mechanical device for the purpose of artificial respiration; there used to be an apparatus of this kind called a lung motor on the market, but I have no personal experience of its employment. It has been urged that the rigidity of the human thoracic cage tells against intermittent perflation, but the pliability of the diaphragm allows sufficient room for pulmonary expansion. W. E. Fisher[3] has practised with success a method of combined massage and artificial respiration; by a series of thrusts with the fingers under the diaphragm he at the same time compressed the heart and expelled air from the thorax. Such a method as this can only be regarded as tentative, and not likely to have a large measure of success; I am convinced that both surgeon and anæsthetist must be absolutely thorough in their methods if they are to justify the performance of massage.†

The Method of Applying Cardiac Compression.

I have tested the effect of varying the rate of compression, and do not myself regard this as a matter of much importance. It is necessary to maintain sufficient circulation pressure in the arteries, so I do not think the rate should be much less than that of the natural beat. The rate of compression bears no relation to that of the spontaneous beat on recovery. Gunn and Martin[5] have found that in the overdosed heart a spontaneous beat develops more readily after a pause in the massage, and they recommend that after a time massage should be intermitted by short pauses. I have independently found that recovery after primary cardiac failure is influenced similarly, a matter to which I will refer again later. The interruption of massage is evidently a point of considerable importance.

Limit of Interval between Occurrence of Syncope and Commencement of Massage.—Posture.

This point appears to be fairly well decided. The limit is not conditioned by any cardiac consideration, at least not mainly, for the heart possesses remarkable powers of recuperation after prolonged periods of suspended circulation. The limit is a quite narrow one and is set by the length of time that the nerve centres can stand deprivation of blood; if this interval is too long, severe nervous symptoms supervene on restoration of the circulation, such as tetany, rigidity, screaming, incontinence of urine, and signs of severe cerebral irritation, and these generally terminate fatally. Evidently A. E. Russell's[11] limit of five minutes is a safe one, and is now generally accepted, but the case need not be regarded as absolutely hopeless after a longer interval; in Mollison's[9] case it was 13 minutes, but the patient only recovered after prolonged and serious cerebral symptoms had occurred. This time limit is within that in which intravascular clotting can occur, so that clotting requires no special consideration.

Partial inversion is no doubt of benefit in assisting the cerebral circulation, and the filling of the heart chambers. There is no experimental evidence to show that it assists recovery in any other way.

Chloroform Syncope.

The foregoing principles have a general application to cardiac massage under any circumstances. In chloroform narcosis two principal forms of syncope require some separate consideration.

1. *Syncope from Overdosage.*—In this form of syncope both the heart and respiratory centre are affected by the excess of chloroform, but the respiration fails first, and the heart subsequently, partly from the effect of the chloroform and partly from lack of oxygen. The heart's action is never totally suppressed by an overdose and it continues to beat, faintly it is true, but yet without doubt sufficiently to maintain a measure of pulmonary and coronary circulation; artificial respiration can thus restore the heart beat, first by supplying much needed oxygen, and secondly by causing exhalation of the excess of chloroform. It is my personal opinion that recovery can always be effected by artificial respiration alone when the latter is promptly applied, as probably it always is, but I recognise that if it be neglected the heart becomes totally asphyxiated and incapacitated and may not then be amenable to this treatment. In such an exceptional circumstance cardiac massage would be called

---

† I presume the anæsthetist devotes his attention to the pulmonary ventilation.

Nesslerization of resultant ammonia. It was found to be convenient, rapid, and very constantly accurate, controlled by the usual Kjeldahl.

The excretion of acetone bodies, ketosis, is frequently associated with acidosis in supposed disturbance of the carbohydrate metabolism. Wishing to eliminate a possible ketosis as a factor in any condition of acidosis found to be present, we systematically examined all urines, both of controls and rachitic children, for acetone by Rothera's test on the day of the first examination. Acetone was absent in all cases, with the exception of one of the control cases, which was discarded.

Results.

For the purpose of tabulating results the children have been arranged according to age. From the control list of healthy children (Table I.), it will be seen that in the healthy child the ammonia ratio is roughly constant, approximating to the adult proportion of 5 per cent., average 6·2 per cent. The alkaline reserve is graded B or C—i.e., these children originally had an acid urine, but a dosage of gr. v. or gr. x. sodium bicarbonate was sufficient to turn it alkaline. Cols. 5 and 6 are of minor importance. They show the reduction in ammonia content (grammes per 100 c.cm.) under the influence of bicarbonate dosage, from the time of the original specimen until the reaction to litmus was changed. Owing to the varying concentration of urinary specimens from day to day, the comparison for these two columns is not a precise one. Generally speaking, however, there was a reduction of upwards of one-half on the content of the original specimen.

The control list of unhealthy (actually convalescent) children (Table II.) shows a definite increase in the ammonia ratio, which is, of course, known to be a very variable quantity in ill-health in early childhood. Average of this list = 10·5 per cent. Three series of rachitic children are shown: Table III., active cases, 13; Table IV., recovering cases, 14; and Table V., healed cases, 3. For all practical purposes the three children classified as healed rickets in Table V. rank with the controls. The average ammonia ratio was 5·9 per cent. and the grade of alkaline reserve was C. Two of these cases were seen by me just previous to their discharge from hospital, *after six months and one year respectively of in-treatment.* The third, I. C., was an *older* child, 4 years, who was admitted for double femoral osteotomy for genu valgum. She was otherwise healthy and normal.

Active Cases.

The series of active cases (Table III.) consists necessarily of the younger children, 8 months to 1 year and 4 months, actually, with acute manifestations of the disease. The clinical condition consisted of flabby musculature, associated with enlarged epiphyses, craniotabes, delayed dentition, sweating about the head, and in many of the cases bronchitis and laryngospasm. P. O'N. and Ch. C.

I. C. ..	4 4/12	0·68	0·0346	5·1	C	0·0300 ,, 0·0272

Average ammonia ratio = 5·9 per cent.
Grade of alkaline reserve, C.

---

* In the control cases only partially recorded, owing to their mothers being out of work, the children unfortunately ceased to attend the nursery before the investigation was complete. When, as in the majority of these cases, the investigation of the alkaline reserve had been done first, a week was allowed to elapse before the ammonia ratio was taken, in order that the effects of alkali dosage might wear off.

† Column 4 contains "whole-day" specimens; column 7 contains single specimens taken late in the afternoon (during period of dosage). A few cases curiously show an increase with dosage. This was also the case with many of the cases of active rickets, as though the alkali dosage actually helped them by encouraging their own reaction—i.e., the production of ammonia.

incidentally such an experiment shows how mechanical stimulus plays no part in the resuscitation of the normal beat. The recovery from fibrillation is sudden and characteristic; the first beats are sufficiently powerful to cause the blood pressure to mount up rapidly (Fig. 2), for the heart has not been depressed by an excess of chloroform.§

Sometimes a temporary cessation of fibrillation occurs within the first few minutes of onset, but the heart cannot beat because it is asphyxiated, and fibrillation is soon resumed. If such a period happens to be hit upon when commencing massage, recovery is easy and rapid, but the beats are first feeble and gain strength slowly, for it is a recovery from simple asphyxia. Apart from this happy chance the length of interval between syncope and the commencement of massage is not of great importance in relation to the rapidity of cardiac recovery, at least up to a limit of 15 minutes. The duration of massage is fortuitous; it varied from one up to 48 minutes in a series of 20 cats upon which I experimented. The following table shows my results *in extenso*. Every case had a successful issue, so that the absolute efficiency of massage for fibrillation in cats is remarkable.

Results of Massage for Fibrillation in Cats.

(A) Shows interval in minutes from moment of syncope to commencement of massage.

(B) Duration of massage before ventricular beat returned.

(A)	(B)	(A)	(B)
2 ..	19 min. 30 sec.; 20 sec.*; 1 min. 10 sec.*; 1 min.*; 9 min. 35 sec.; 1 min.*; 4 min.; 12 min. 30 sec.	5 ..	30 sec.*
2½..	2 min.; 4 min. 30 sec.; 9 min.	7 ..	48 min.
3 ..	16 min.; 5 min. 30 sec.; 20 sec.*; 2 min. 50 sec.	8 ..	22 min. 25 sec.; 6 min. 10 sec.
4 ..	3 min.	9 ..	23 min.
		10 ..	3 min. 15 sec.; 5 min. 40 sec.
		11 ..	4 min.
		12 ..	8 min.
		13 ..	4 min. 10 sec.; 7 min.
		15 ..	24 min. 30 sec.

* In those experiments marked by asterisks fibrillation was in abeyance when massage was commenced.

The blood pressure on recovery from fibrillation is nearly always satisfactory; should it be unsatisfactory an injection of pituitrin will improve it very much.

Use of Drugs.

McWilliam[8] tested the action of adrenalin and a number of other drugs upon the fibrillating ventricles; he used them in conjunction with massage and obtained successful results. I have repeated most of these experiments, but in my experience the results of massage alone are equally good, and I have so far been unable to convince myself that any of the drugs are of real service. Further research is desirable upon the subject, but for the present drugs are better left alone; the drug that will stop fibrillation is yet to be found.

It is for the treatment of primary cardiac syncope from ventricular fibrillation that cardiac massage finds its most urgent application. If a patient fails to recover spontaneously from fibrillation within two minutes massage becomes imperative, for there is no other remedy. I think I may claim to have demonstrated the effectiveness of this remedy; the treatment of ventricular fibrillation by this method in cats has been shown to be consistently successful, and I believe similar results can be obtained in man. It must, however, be admitted that the conditions are not so favourable in man. In animal experiments the chest is laid open and the heart made thoroughly accessible; it can be compressed by the fingers without undue fatigue, the efficiency of massage can be judged by inspecting the colour of the left auricle, the lungs are seen expanding and the efficiency of the artificial respiration can be gauged, and the nature of the fibrillary movements can be inspected. In man there must be some difficulty in getting at the heart and efficiently embracing the ventricles in the grasp, and fatigue of the operator's hand is an element which is not negligible in a prolonged case. The proposition in man seems to me a somewhat different one and occasional failures must be expected, but with a proper knowledge of the principles involved and their careful application very much better results may, I am persuaded, be obtained in cases of massage than has hitherto been the case.

Rules for Performance of Cardiac Massage in Chloroform Syncope.

(*a*) In syncope from overdosage. Partial inversion and immediate artificial respiration by Sylvester's method. If recovery does not occur within three minutes, artificial respiration alone is not likely to avail. Proceed after three minutes to perform intrathoracic massage with perflation of the lungs. (*b*) In syncope from primary cardiac syncope. Partial inversion for two minutes (with artificial respiration if the diagnosis is not quite certain). If spontaneous recovery does not occur within two minutes, proceed at once to intrathoracic massage, with perflation of the lungs. (*c*) In the interest of the nerve centres cardiac massage should be commenced within five minutes of syncope. (*d*) Success depends upon proper access to, and the efficient compression of both ventricles, and an efficient system of artificial respiration. (*e*) If continued rhythmic compression is not successful in five minutes, it should be intermitted for periods of up to 45 seconds' duration. (*f*) Massage should be continued, if necessary, up to one hour's duration before abandoning the case. (*g*) It is advisable to rely throughout on massage alone and discard the use of drugs. (*h*) If the circulation is feeble after recovery, an intravenous injection of pituitrin is desirable.

§ Fibrillation does not occur in full chloroform anæsthesia.

A NOTE ON THE INVESTIGATION OF GASTRIC FUNCTION BEFORE AND AFTER GASTRO-JEJUNOSTOMY.

BY T. G. D. BONAR, M.B., B.S. LOND., M.R.C.S.,
SURGICAL ASSISTANT AND DEMONSTRATOR OF ANATOMY, GUY'S HOSPITAL.

IN obtaining these notes on the effects of gastro-jejunostomy on gastric secretion use has been made of the fractional test-meal as described by J. A. Ryle[1] and J. H. Ryffel,[2] the pioneer being Rehfuss.[3] All types of case have been examined—e.g., gastric and duodenal ulcers, carcinoma of the stomach—where a gastro-enterostomy has been performed, alone or together with a partial gastrectomy. The notes may give an indication as to what one anticipates will occur in a large series of each type of case. Such a complete paper will be published ultimately.

Ryffel has described the relative merits of the two methods of test-meal examination of the stomach, and Ryle has published his facts on the fractional test-meal for the diagnosis of gastric and duodenal lesions, and also his series of normal curves. Use was therefore made of the latter type of meal to arrive at a diagnosis before operation, together with a chemical examination of the fæces and also a barium meal examination of the stomach; notes were made about the lesion found at operation and of what was done; and after six months the patient was re-examined by X rays and by test-meal.

Four types of curves are shown in this paper: (1) Prepyloric gastric ulcers; (2) pyloric ulcers; (3) duodenal ulcers; (4) carcinoma of the stomach. The first curve, for comparison, is one of a so-called normal type (Fig. 1).

Group 1: Prepyloric Ulcers.

B. B., female, aged 46 years, had complained for two years of frequent attacks of indigestion; pain of a gnawing character usually came on about 35 minutes after taking to a diet of cow's milk (containing an excess of calcium salts) the usual empiric treatment in this country.

[1] THE LANCET, 1920, ii., p. 490. [2] Ibid., 1921, i., p. 586.

[3] Amer. Journal of Science, 1914, Ch. 147, p. 848.

The presence of an acidosis in rickets calls for careful prophylactic measures, along lines likely to prevent such a condition, whether it be the determining factor in the disease or otherwise. Treatment on these lines has been excellently outlined by Pritchard.[14] It includes the correction of faults of dietary, more particularly overfeeding, provision for adequate exercise, surface stimulation by baths and fresh air, relief of respiratory embarrassment from whatever cause, and the avoidance of infections—catarrhal or otherwise—in so far as this can be arranged. Remedial measures must include the treatment of the underlying condition—that is, the treatment of an acidosis from whatever cause it has arisen.

In conclusion I have to thank Prof. Ramsden, Dr. Ruby McBirnie, the staff, medical and nursing, of the Liverpool Day Nurseries and of the Leasowe Hospital, and Dr. Phœbe Bigland for help at various stages of my work.

WORTHING CHILDREN'S CARE SOCIETY.—Dr. R. H. Wilshaw, M.O.H. of Worthing, addressed this society at its annual meeting on Oct. 17th. He said that 12 years ago, when the society was first formed, the infantile mortality-rate of Worthing was over 100. In five or six years the rate was halved; in 1920 the figure was down to the record level of 39. These figures provided a sufficient answer to those who said there was no need for a Children's Care Society. Dr. Wilshaw attributed the fall in infantile mortality largely to the influence and work of this society and of the Infant Welfare Centre, and emphasised that the object of the two organisations was to keep healthy babies healthy, and not to cure sick ones.

SOUTH-WESTERN OPHTHALMOLOGICAL SOCIETY.—A meeting of this Society was held on Oct. 24th at the Eye Hospital, Bristol. After an exhibition of cases of interest Mr. Ransom Pickard opened a discussion on the Development of Normal and Abnormal Disc Cups, drawing particular attention to the need for systematic record of the dimensions of the disc cup; it should be available for future reference and comparison in the event of subsequent morbid developments within the eye. He brought forward a method for the charting of these data. After the meeting the members dined together at the Grand Hotel. An invitation to meet the Midland Ophthalmological Society next April in Birmingham was received from its President, Mr. Bernard Cridland, and accepted.

CARDIAC MASSAGE.*

BY A. G. LEVY, M.D., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

THE principles underlying massage of the heart are very much the same for whatever condition it is applied. I propose first to state these general principles, and later to discuss the employment of massage in chloroform syncope, a form of syncope with which I am most familiar from an experimental point of view, and a form which is, I think, of more interest to the surgeon than any other. The conclusions at which I have arrived are mainly the outcome of a recent investigation, and whilst I have some things to say which are new, a good deal is not new, but is in agreement with and serves to confirm the opinion of others.

J. A. Gunn[4] has recently published a paper in which he lays down certain physiological principles for guidance in performing massage, and whilst I am in accord with much that he has written, his paper requires expansion, for he deals with one form of chloroform syncope only—viz., that from overdosage—whereas primary cardiac syncope is the condition which calls most urgently for the application of this method of resuscitation.

I think that the small number of cases in which cardiac massage has been practised with a successful result are sufficiently well known to excuse further comment upon them, but I am sure that the large number of the unsuccessful attempts is unappreciated; they are, in fact, almost sufficiently numerous to bring cardiac massage into disrepute. This is not as it should be: I am therefore showing how consistently successful results are obtained in animals, and giving my reasons for the belief that similar results can be obtained in man. The sole function of cardiac massage, as I maintain in common with others, is to create an artificial circulation; to perfuse the lungs, and to supply the heart and central nervous tissues with oxygenated blood in order to preserve their function. This view has been brought forcibly home to me in my special work.

"Massage" a Misnomer—Massage and Mechanical Stimulus.

The term "massage" is a misnomer; it is not massage of the muscular tissue of the heart which is required, but a rhythmical compression of the heart efficient in expelling with fair force the contents of both ventricles; the right ventricle must be compressed as well as the left, and I have not found my experimental results to be consistently satisfactory unless this point receives careful attention. Obviously a good supply of oxygenated blood to the left ventricle can only be obtained by emptying the right. In the human heart the hand must therefore have ready access to the right ventricle, and this is one of the points in surgical technique which tend to turn the scale between success and failure.

I may digress for a moment to a point of more academic interest. Gunn[4] maintains that massage also acts as a mechanical stimulus to the heart beat; it is, however, difficult to see how this can be, or to agree that sufficient reason has been given in support of this view. Personally I believe massage is deleterious to the heart beat and I think Gunn and Martin's[5] own experiments may be interpreted as bearing out this point of view; the heart beat is most certainly not initiated in cases of ventricular fibrillation (see Fig. 2) by mechanical stimulus, and I think this theory should be entirely disregarded in considering practical methods.

Surgical Technique.

The technique of obtaining proper access to the heart and compressing it is evidently of great importance; direct access to the heart appears to me to be essential. In a number of recorded cases of the

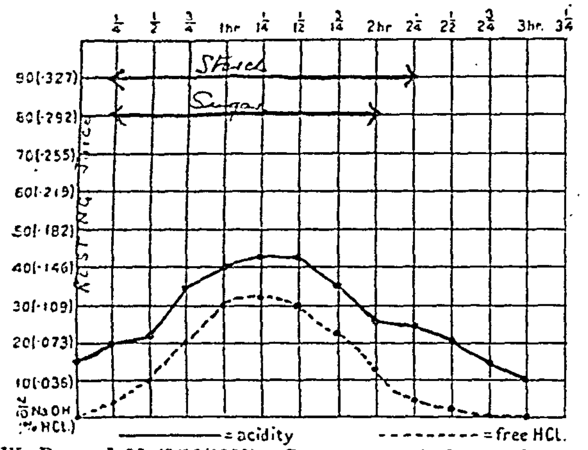
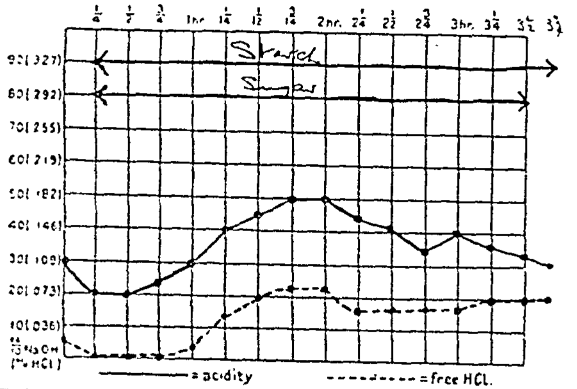
FIG. 1.



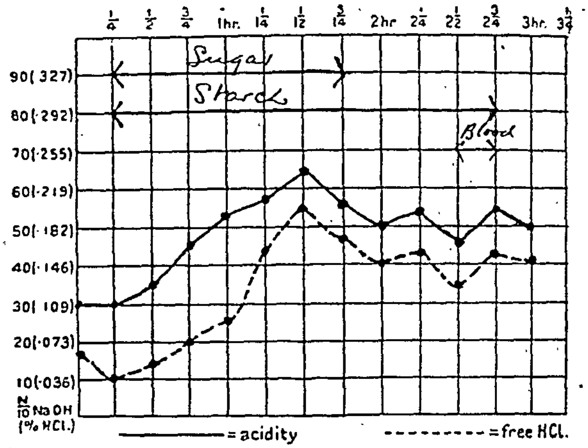
W. B., aged 35 (3/12/1920). Curve of so-called normal type. Note that the rise of free hydrochloric acid and the total acidity does not reach any great level, and that the stomach is emptying in normal time (2¼–2½ hours) as indicated by the sugar and starch estimation. Any other constituent present—e.g., bile or blood—will be found charted on the curves.

FIG. 2.



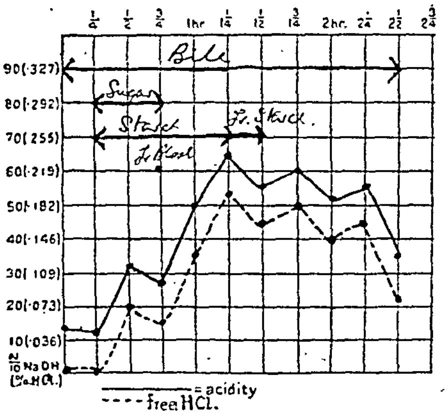
B. B., aged 46 (3/11/1920). Before operation. Note the delay in emptying of the stomach and slow rise of acid.

FIG. 4.



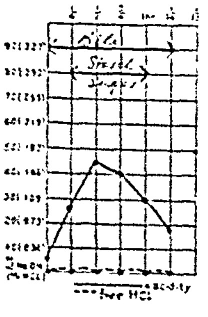
T. G., aged 27 (10/6/1920). Pyloric ulcer. Note stomach late in emptying; hyperchlorhydria; presence of blood.

FIG. 5.



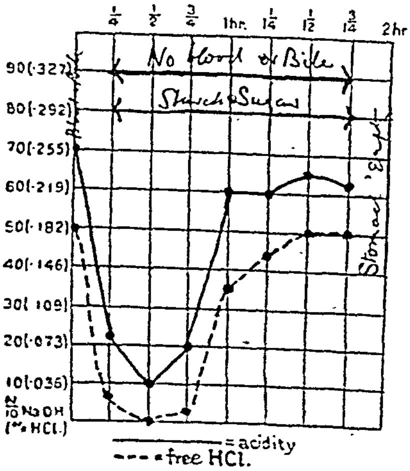
Same patient as Fig. 4 (14/1/1921) after gastro-jejunostomy. Note stomach emptying rapidly; bile present; maximum total acidity and maximum free hydrochloric acid reach same level before and after gastro-jejunostomy.

FIG. 3.



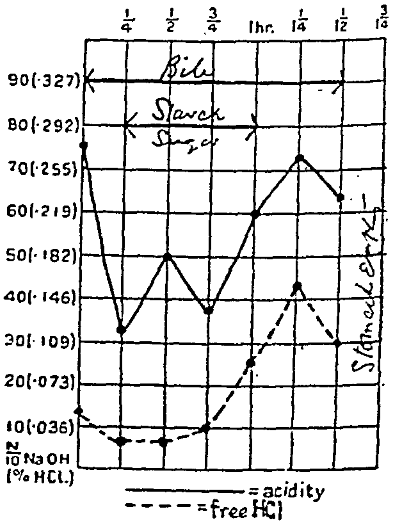
Same patient as Fig. 2 (11/3/1921) after gastro-jejunostomy. Note the rapid rate of emptying of the stomach and the presence of bile; no free hydrochloric acid. Total acidity reaches 46 (cf. before operation 50).

FIG. 6.



T. C., aged 45. Duodenal ulcer before operation. Note highly acid resting juice, rapid emptying of stomach; hyperchlorhydria.

FIG. 7.



Same patient as Fig. 6. Duodenal ulcer after gastro-jejunostomy. Note high total acidity resting juice, but the free hydrochloric acid is diminished. During the meal the total acid reaches as high a level as before operation, whereas the free hydrochloric is slightly diminished. Bile present throughout; rapid emptying of stomach.

for. The adequacy of massage to restore the beat of the overdosed heart has been fully proved; my personal experience in experiments on cats has been a rapid success in all cases, even in hearts artificially overdosed to the complete extinction of the ventricular beat. The heart recovers from an overdose in a characteristic fashion. The beat is at first very feeble and may require further massage to improve it. Thenceforth improvement in both beat and blood pressure is gradual and progressive, consistent with the view that the heart gains in strength as the blood excretes its chloroform (Fig. 1).

Jones[6] following the injection of adrenalin under chloroform were certainly due to ventricular fibrillation, yet they all recovered without treatment; a number of reports of spontaneous recovery from primary cardiac syncope in chloroform anæsthesia are found in the pages of the Report of the Anæsthetic Committee of the British Medical Association, and in these instances there can be little doubt fibrillation had occurred.

I am laying stress upon this tendency towards spontaneous recovery from fibrillation in man, because it is correlated with success in the practice of cardiac massage, massage being merely a means of saving the heart from asphyxia, and affording it a prolonged opportunity of exerting its natural tendency to recover spontaneously. In dogs there is little of this tendency, and attempts at resuscitation by massage generally terminate in failure. In cats, on the other hand, there is a conspicuous tendency towards spontaneous recovery, and in these animals I have found cardiac massage consistently successful. I therefore class man in the same category as the cat, in respect of the successful issue of massage. In cats spontaneous recovery always occurs whilst the heart is still vigorous and the fibrillary movements active—that is, within the first one and a quarter minutes from the moment of syncope; it cannot occur later when the heart has become asphyxiated. On perfusing the heart with oxygenated blood by massage with artificial respiration the active fibrillation is sustained until sooner or later, provided massage is continued sufficiently long, the fibrillary movements are replaced by the normal sequential beat.‡ The practical lesson is obvious: not more than two minutes should be allowed for the chance of spontaneous recovery following primary cardiac syncope in man and thereafter cardiac massage should be proceeded with without hesitation. If recovery has not been effected after five minutes of continuous massage, this should be intermitted by a pause of about 15 seconds, later extended to 45 seconds, and this procedure may be found successful either during the pause or on resumption of massage. A pause appears to rest the heart from the depressing influence of manipulation, for it results in increased fibrillary activity. An illustration of this event is shown in Fig. 2;

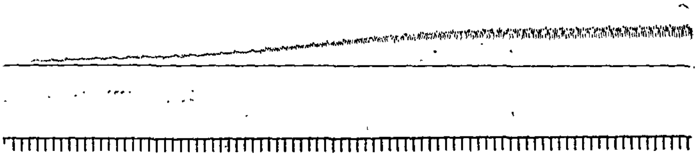


FIG. 1 (full size).—Blood-pressure curve from an experiment upon a cat. Hurtlé manometer, time marked in seconds. *The heart had been overdosed with chloroform to extinction of the beat.* The heart beat was restored by massage and artificial respiration, and the tracing shows the characteristic gradual improvement of beat and blood pressure which occurs after an overdose.

Gunn[4] recommends washing adrenalin into the heart through the jugular vein before commencing massage, but it cannot enter the coronary circulation unless the heart is beating, when it is not wanted, or until the commencement of massage, which succeeds without it. In my own experimental experience adrenalin has no beneficial effect upon a heart which has been overdosed with chloroform to the extinction of its function, so that it does not appear to me that the risky combination of adrenalin and chloroform is justified by any theoretical consideration. If the blood pressure is low following recovery, then pituitrin should be injected, not adrenalin, for the latter is dangerous to the heart which has thrown off its excess of chloroform. I can confirm Gunn and Martin's observation that although the action of the vasoconstrictor agent be temporary, the effect in such circumstances tends to be a permanent rise of pressure.

2. *Primary Cardiac Syncope.*—In this form of syncope the respiratory centre is not depressed by the chloroform, and the respirations continue for a short period after the stoppage of the heart, but the respirations fail likewise shortly afterwards owing to cessation of the circulation. Neither is the heart depressed by the chloroform; it fails *quite suddenly* from the onset of ventricular fibrillation in the course of full activity. Sometimes the respirations are exaggerated immediately before they finally cease, sometimes there is a spasm of the whole body; sudden pallor and extreme dilatation of the pupils also help to identify this form of syncope. Ventricular fibrillation has generally been regarded as necessarily fatal, but this is by no means the case; that recovery may occur in man is proved by the electrocardiographic record obtained by Robinson and Bredeck,[10] and there is indeed in my opinion clinical evidence that spontaneous recovery is more common in man than a fatal termination. Three cases of serious syncope noted by Seymour

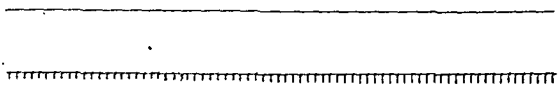

FIG. 2 (full size).—Blood-pressure curve from an experiment on a cat. Hurtlé manometer. Time marked in seconds. Resuscitation of the fibrillating ventricles by cardiac massage combined with artificial respiration. The tracing shows two periods of massage, 1 and 3, and two pauses, 2 and 4. The heart recovers during a pause. The recovery from fibrillation, 5, is characteristically rapid, and contrasts vividly with the gradual recovery after overdose.

---

‡ Recovery from fibrillation is not merely a recovery from inactivity, as it is in the case of overdosage. The normal beat is not superposed on fibrillation, and the latter must cease before recovery can take place; there is a momentary phase of inactivity interposed.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF
CYSTICERCUS CELLULOSÆ IN MAN.

BY JAMES R. HUGHES, M.A., M.B., B.S. DURH.,
PHYSICIAN TO THE MINISTRY OF PENSIONS HOSPITAL, NEWCASTLE-ON-TYNE.

THE following case of *Cysticercus cellulosæ* occurring in an army pensioner is of sufficient rarity and interest to merit record.

J. V. B. was admitted to this hospital on Jan. 24th, 1921, with the invaliding disability of malaria and an indefinite history of fits. During the routine case-taking examination of this patient it was found that he had what appeared to be several subcutaneous nodules, varying in size from that of a pea to a cherry. The body distribution was as follows: One at the angle of the right lip, three on the front of the chest, 15 on the back and posterior aspect of the neck, and five on each of the arms and legs. As the nodules seemed roughly to follow the line of the cutaneous nerves a provisional diagnosis of multiple neuro-fibromata was made pending the removal and examination of one of the nodules.

On the 30th three of the small tumours were excised. During the process of removal it was found that the nodules were intramuscular cysts, being covered by a few muscle fibres, subcutaneous tissues, and skin.

Following is a description of the condition found:

(1) Each individual cyst really consisted of two, an ectocyst and an endocyst. The wall of the ectocyst was composed of dense fibrous tissue, reactive from the patient.

(2) On opening the wall of the ectocyst about half a c.cm. of serous fluid escaped and the endocyst was exposed; this was the true *Cysticercus cellulosæ*.

(3) The wall of the smaller cyst—i.e., the *Cysticercus cellulosæ*—was the caudal vesicle of the worm, into which the worm's head and body were invaginated like a glove turned partly inside out. We were able, by gentle pressure, to evaginate these parts of the worm from its caudal vesicle, through a very small aperture in the cyst wall. The head carried four suckers and a rostellum armed with a double row of chitinous hooks.

Signs and symptoms.—The patient complained: (*a*) That he had fits, about one every four weeks; (*b*) that whenever he had a high temperature, whether from malaria or from other causes, the "little lumps" become very sore. With regard to the fits, he was observed in three of these during his stay in hospital; they were not epileptiform in character, but were more like vertigo. There were no localising signs of a cerebral tumour; the patient's cranial nerves, as well as his deep reflexes, were quite normal. There was no history of headaches, or of vomiting, nor was there any error of refraction present; the fundi oculi were quite normal. Several blood counts were taken: an average of these showed red blood corpuscles 5,675,000, white blood corpuscles 11,375, and of the white blood corpuscles 20 per cent. were consistently eosinophiles.

History.—A brief account of the patient's life before his admission to hospital may be of interest. Born in London, in 1885, he lived there until 1908, employed for some years as a horse-breaker; he was always healthy. He joined the Regular Army in 1908 and went direct to India, where he was stationed for six years, during which period there was no history of any illness. He stated that he never bathed in rivers or lakes, but that when in India he used to drink rain-water. He returned to England in 1914 and was drafted to Salonica in 1917; at this latter place he contracted malaria in 1918. During the latter year he noticed "little lumps" forming in the skin of his face and on the back of his neck.

Treatment.—In addition to treatment of the malaria every attempt was made to rid the patient of the cysticerci. A concentrated couse of intravenous neokharsivan was given without any apparent benefit. Following this a course of antimony tartrate intravenously was tried, but with little or no appreciable result. The third method of treatment was purely local and was of some benefit; it consisted of puncture of the superficial cysts with a hypodermic needle and injection of carbolic acid in glycerine (20 per cent.) into them. A brisk local reaction occurred, but it was followed by the disappearance of the cyst in a day or two. Unfortunately, it was only the most superficial cysts that could be treated in this way. In all 18 cysts have been destroyed, but numerous others are probably present in the deeper tissues.

Mode of infection.—It is an acknowledged fact that if man eats "measly pork"—viz., pig's muscle in which *Cysticerci cellulosæ* are embedded—he will develop the adult *Tænia solium*, which will live as a parasite in his intestines. If, however, he unfortunately ingests, either in his food or drink, the ova or an egg filled segment of the *Tænia solium* he stands a chance of infection with the encysted embryonic form (i.e., *Cysticercus cellulosæ*) of the tape-worm, and may himself become "measly." Man seems to be particularly immune from this condition, and I have only been able to trace six prior brain-cases in the literature [1] as having occurred in Great Britain. When, thus rarely, the ripe ova of the tape-worm find their way into the human stomach their shell is dissolved by the gastric juice; the freed embryos pass, by means of their hooklets, through the walls of the stomach or intestines, and are dispersed by the blood-stream into all parts of the body, but they seem to have a particular tendency to settle in the brain, spinal cord, and the inter-fascicular connective tissue of the muscles. Küchenmeister, whilst experimenting on condemned criminals in 1855,[2] and Leuckart in 1856, found that auto-infection could occur—viz., that a patient harbouring tape-worms could infect himself with *Cysticercus cellulosæ* either by contaminating his food-stuffs with hands soiled with ova, or by regurgitating the ova or ripe segments of the worm during the act of vomiting.

Exactly how this pensioner became infected is purely a matter for speculation. He had never, to the best of his belief, passed a tape-worm, and certainly did not pass one during his stay in hospital, as his stools were most carefully examined, against a dark background, after the administration of large doses of anthelmintics. It is possible that he ingested the ova or a ripe segment of a tape-worm in the rain-water that he used to drink whilst in India.

I am permitted to publish these notes by the kind permission of Colonel F. J. Greig, C.M.G., A.M.S. (R.), medical supt. of the hospital, and of Dr. D. Wells Patterson, the consulting physician.

I am indebted to Dr. P. C. Laws, bacteriologist to this hospital, and to Mr. T. W. Flattely, lecturer in zoology at Armstrong College, Newcastle-on-Tyne, for their kind help in examining the cysts with me, and for making serial microscopical sections of them.

A CASE OF GENERAL INFECTION BY
CYSTICERCUS CELLULOSÆ.

BY H. K. ABBOTT, M.D. DUB., D.P.H.,
MEDICAL SUPT., MENTAL HOSPITAL, KNOWLE, FAREHAM.

THE following case of general infection by *Cysticercus cellulosæ* is sufficiently uncommon to be of interest. The disease was believed to have been contracted in India.

A female patient was admitted to the Mental Hospital on July 13th, 1918, suffering from melancholia and with a history of headache and dimness of vision for two months, having also had two fits with transient weakness of left side a fortnight before admission. Her general condition was fairly good and she talked rationally but was very depressed. She complained of pain on left side of head; there was deafness in left ear; sight in both eyes was so diminished that she could not read newspaper headings; no sign of hemiplegia. There were numerous small shotty sub-food, lasting for about five hours; it was not alleviated by taking food or medicine. She never had had hæmatemesis, and only on rare occasions did she vomit. In the last three months she had lost a considerable amount of weight; this loss she ascribed to her inability to take food for fear of the pain it would cause her. Physical examination showed the patient to be thin and wasted, but no abnormality was detected on palpation. Test-meal showed that her rise of acid was slow and that her rate of emptying was also slow. This pointed to gastroptosis, but as the fæces contained altered blood, as shown by an acid hæmatin spectrum and a positive guaiac reaction, it was decided that she might have a prepyloric ulcer with adhesions.

X ray examination of the stomach—carried out with all other X ray examinations recorded in these notes by Mr. J. Magnus Redding, surgical radiographer to Guy's Hospital, and by whom all X ray examinations published in these notes were performed—resulted in the following report: "Stomach deeply ptosed and is hypotonic, and contains a good deal of fluid. The motility is poor. There is a projection from the posterior surface of the stomach near the lesser curvature in the prepyloric position. ? an ulcer. The duodenum shows considerable deformity, suggestive of adhesions." Note that the diagnoses arrived at by test-meal and X rays are practically identical.

An operation was performed a few days later and a prepyloric gastric ulcer on the lesser curvature of the stomach was found. The greater omentum was bound down to the pelvis, a fact due to a previous operation (hysterectomy) performed; and so this binding down of the stomach via the greater omentum caused a certain amount of gastroptosis. Posterior gastro-jejunostomy was performed; the patient made an uneventful recovery.

Six months after her discharge from hospital I saw patient again and carried out another test-meal examination. She stated that she had had no recurrence of pain, had put on weight, and felt much better in every way. Test-meal showed that at no time did she get free hydrochloric acid into her stomach, but that the total acidity in ½ hour reached the maximum and was as high as the total acidity before operation, but in this case she had bile in her resting juice, and a great quantity of bile was poured into the stomach during the period of examination. It was impossible to extract fluid after 1¼ hours (stomach empty).

From comparison of the test-meal before and after operation it seemed that: (1) Bile entered the stomach in large quantities; (2) the stomach emptied rapidly; (3) no free acid was obtained ? due to neutralisation from the bile; (4) the total acidity reached the same level as before operation, but the free hydrochloric acid was diminished. These four facts have been found to occur in every case of prepyloric ulcer examined up to the present time.

Group 2: Pyloric Ulcers (with or without Stenosis).

As will be seen from the accompanying curves, before and after gastro-jejunostomy in this type, the total acidity reached in both curves is about the same level, although the time relation may alter and also that the same rule applies to the free hydrochloric acid. The stomach is emptying usually more rapidly, and bile is entering the stomach.

T. G., male, aged 27 years, gave a three years' history of intense pain coming on very quickly after meals, and at first persisting for one hour; but this period later extended so much that in the end the patient had scarcely any interval between the pain of one meal and the pain coming on from the second. In spite of medicinal treatment and dieting patient's symptoms steadily got worse, and in the end became so severe that he was unable to leave his bed. Test-meal examination showed delayed emptying of the stomach as shown by the persistence of starch and sugar; there was also hyperchlorhydria and blood was present. Pyloric ulcer with stenosis was diagnosed. Fæces contained altered blood. X ray examination showed no abnormality.

At operation a large pyloric ulcer stuck down to the pancreas was found, causing pyloric stenosis. In addition there were numerous adhesions to the liver and gall-bladder. A posterior gastro-jejunostomy was performed. Six months after operation patient looked a new man, and felt strong and well. He had put on almost eight pounds in weight, could take any type of food, although he restricted himself somewhat on previous advice, and he had had no recurrence of symptoms.

Group 3: Duodenal Ulcers.

T. C., male, aged 45 years, has had attacks of indigestion for some years. In the last three months the attacks of pain which came on about 1¼ hours after taking a meal had become steadily worse. He was awakened at nights with "hunger pain." In the early stages the taking of food had relieved the pain a little, but in the later stages this had had no effect. He had much flatulence. Physical examination showed patient tender in the epigastrium rather to the right of the mid-line; otherwise no abnormality. Test-meal showed a high resting juice containing bile; during the meal the free acid and total acidity rose to a much higher level than in any curve mentioned before. The stomach was emptying rapidly. Fæces contained altered blood. X ray examination showed presence of an irregularity near the pylorus on the duodenal side.

At operation a duodenal ulcer ½ in. from the pyloric ring was found. A posterior gastro-jejunostomy was performed. Six months later patient was very much better, had put on weight, and had had no recurrence of pain. Test-meal showed bile to be present throughout the whole meal—the resting juice was still high in acidity, the maximum of the curve for total acidity was as high as before, whilst the free acid almost reached the same level. The free acid in the resting juice is diminished in quantity.

Group 4: Carcinoma of the Stomach.

(A) *Partial Gastrectomy and Gastro-jejunostomy.*—Mary W., aged 39 years, had been losing weight steadily for six months, and had begun to get pain on taking her meals. She vomited occasionally, and was now able to take sloppy foods only. Examination showed the presence of a hard movable mass in the epigastrium about the size of a florin. Test-meal showed a low free hydrochloric acid and a moderate curve for total acidity. Blood was also present as coffee grounds. This was taken as an indication of carcinoma. X rays: Stomach showed profound ptosis, the greater curvature lying nearly at the upper border of the symphysis pubis. Motility poor and meal leaving slowly. Pyloric canal elongated with an irregularity. Sixth hour: Some of meal still in stomach. Thirtieth hour: Still some meal in stomach. Fæces, altered blood present.

Operation.—A movable pyloric growth (carcinoma microscopically) discovered. Some enlarged glands along the curvatures of the stomach. Partial gastrectomy, and gastro-jejunostomy (Polya-Mayo method). Six months later patient could eat a hearty meal, and had no pain. She had put on weight—about 7 pounds—and had no vomiting. Test-meal showed the absolute absence of free hydrochloric acid and a very low total acidity curve. The remains of the stomach were emptying quickly.

In the other cases of gastrectomy I have collected there was no free hydrochloric acid in either curve, before or after operation.

B. *Carcinoma Ventriculi: Gastro-jejunostomy only.*—A. C., male, aged 51 years, had been losing weight for about a year. Pain in the epigastrium, present at all times, was getting steadily worse, and it was accompanied by vomiting. Physical examination revealed nothing, but it was noticed that patient was extremely wasted. Test-meal showed great delay in the emptying of the stomach, blood was present, and the free hydrochloric acid was low and late in appearing. Diagnosis was pyloric stenosis, probably due to growth. X rays showed the stomach to be of large capacity, the lower pole being 2 inches below the iliac crest. No irregularity along either curvature, but the barium was leaving slowly. After five hours stomach was a quarter full; no tenderness.

At operation a large pyloric carcinoma was found, and there were secondary deposits in the liver. A posterior gastro-jejunostomy was performed. Subsequent examination showed that patient had been relieved of his pain and that his stomach was emptying in about normal time. A certain amount of bile was present and a positive guaiac was obtained in the stomach contents. The free hydrochloric acid was not present, and the total acidity was lower than in the first meal before operation.

I have also had the good fortune to have two cases of prepyloric ulcer—one treated by excision of the ulcer only, and the other where the ulcer was cauterised and a gastro-jejunostomy performed, and in both cases have the results followed into the prepyloric group. I have also had the better fortune to have the pre- and post-operative results of three cases of gastro-jejunal ulcer following a previous gastro-jejunostomy. In each case after excision of the gastro-jejunal ulcer, the previous curve being of the duodenal ulcer type, the second curve has followed into the same group—i.e., the duodenal ulcer grouping.

Conclusion.

The indications at present arrived at seem to show that—

(*a*) Ulcers can be grouped under three headings: (1) Prepyloric, including cardiac ulcers; (2) pyloric urine for examination. The modern patient led his life in much greater comfort, and we were justified in believing that as long as he conformed to treatment his expectation of life was much increased. These were no small gains; but, concluded Sir Archibald Garrod, whilst our control of the malady was now much more efficient we were unfortunately still as far as ever from being able to cure our patients.

Mild and Severe Types of Diabetes.

Sir WILLIAM WILLCOX said that cases of diabetes varied enormously in severity, the milder types being more commonly treated by the general practitioner, while hospital cases were, as a rule, of the severer type. The milder type, called by Pavy "alimentary diabetes," could be recognised clinically by the condition of the patient, who did not exhibit wasting, and in whom thirst and polyuria were not marked. Usually acetone and diacetic acid were absent from the urine, although sugar might be present in high percentage. In cases of this type treatment by a short period of fasting quickly banished sugar from the urine, and the carbohydrate tolerance was then gradually determined by a graduated dietary of known carbohydrate content. Sugar should not be permitted, and the treatment of such cases consisted in so regulating the diet that the urine remained sugar-free. Sir William Willcox said that certain cases of this type occurring in well-nourished and plethoric patients only exhibited glycosuria after such indiscretions in diet as alcohol or excess of meat, quite apart from carbohydrate. A careful regulation of all the constituents of the diet should be insisted on, and toxic causes of glycosuria sought for and removed. The severe type of diabetes was associated with a more or less complete impairment of the pancreatic function of control of the carbohydrate metabolism. In very severe cases pancreatic control appeared to be permanently lost. Such cases were incurable, although the symptoms might be to a great extent alleviated. The pancreas from its deep-seated position in the body was incapable of physical examination, and irreparable damage might occur to the islands of Langerhans without any warning. No premonitory symptoms such as occur in the case of the liver became evident, and glycosuria was the first sign of damage which had already been effected.

Toxic Foci to be Removed.

The first step in the treatment of diabetes should be the detection and removal, if possible, of the cause; and the true cause of diabetes was damage to the pancreas by some toxic agent, in many cases no doubt bacterial. Sir William Willcox had seen severe glycosuria associated with carbuncle disappear after successful treatment of the septic lesion. In such a case it appeared that the toxins absorbed caused temporary arrest of the pancreatic function. Temporary glycosuria was well known in mumps, and numerous cases of glycosuria in syphilis had been cured by anti-syphilitic treatment. In several of the speaker's cases of diabetes bacteriological investigations had revealed abnormal intestinal infections. In one case the stools contained an excess of pathogenic streptococci and a non-lactose-fermenting Morgan's bacillus. In this case there was a history of catarrhal jaundice followed three months later by severe influenza, glycosuria being accidentally discovered six months later. Sir William Willcox did not think that the importance of the removal of possible toxic foci had been sufficiently realised in the treatment of diabetes. In every case it was of the utmost importance to make a most careful search. Examination of the tonsils and naso-pharynx, X ray examination of the teeth, bacteriological examination of the stools and urine, the Wassermann test, and so forth, should all be carried out, and any source of toxic poisoning found appropriately treated. Unfortunately many of the severe cases of diabetes were not seen until the pancreas had already suffered irreparable damage, and in such cases little could be expected from treatment.

The Routine of Treatment.

Sir William Willcox said that during the last two and a half years all his cases of diabetes at St. Mary's Hospital had been treated on the lines laid down by Allen and Joslin. Glycosuria had been removed in all cases, and marked improvement had occurred in all but one patient, who also suffered from advanced phthisis. During the patient's stay in hospital the carbohydrate, protein, and fat tolerance was determined and alternative diets were drawn up which were well below the limits of his tolerance, so that the regulation of the dietary had been possible after the patient left hospital. The patient was further instructed to test the urine, and carry out regular fasts; with occasional supervision glycosuria had either been prevented or at least kept under control. In severe cases with low carbohydrate tolerance, two ounces of whisky might be added to the diet, thus providing a much-needed 210 calories, and giving the patient a sense of well-being. Alcohol should not be given on fasting days, and was best avoided in milder cases. The early signs of acidosis should always be carefully looked for and fat and protein withdrawn from the dietary and carbohydrate reduced to 1 g. per kilo. of body-weight in the form of oatmeal and orange juice. Alkalies, although they did not neutralise the toxic group in aceto-acetic acid, helped by increasing the CO_2 elimination. He gave citrate and bicarbonate of soda in doses of 40 gr. every two hours in cases of threatening acidosis, with beneficial results. During the last year, at the suggestion of Prof. B. J. Collingwood, he had given glucose solution by the rectum in 10 severe cases. The amount of glucose so administered greatly exceeded the carbohydrate tolerance, but in no case did glycosuria result. Analyses of the fluid in the rectum made it clear that more than 25 per cent. of the glucose had been absorbed. He thought this might be useful in cases of acidosis with threatening coma. Drugs were not usually needed, other than alkalies for acidosis, but Sir William Willcox said he had found codeine in doses of ½ to 1 gr. t.d.s. useful in controlling the glycosuria in patients who must of necessity carry on their work.

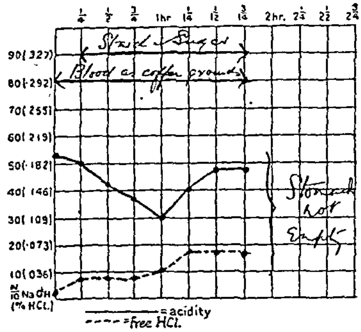
Three Groups of Patients.

Dr. O. LEYTON said that for purposes of treatment patients suffering from diabetes mellitus should be divided into three groups. The first group consisted of patients who had comparatively recently developed the disease, were over 40 years of age, and in all probability came into this world with undersized pancreases and oversized appetites. After years of overwork the pancreas began to degenerate. This degeneration might be arrested if the work thrown upon the gland were decreased. Allen's experiments upon dogs, from which he had removed fractions of the pancreas, suggested the existence of this group. Allen found that a dog could live with one-sixth of its pancreas intact provided it was not overfed; whilst a dog with half its pancreas could be made to develop diabetes mellitus and die from it, provided it was systematically overfed. One might assume that the individual developing diabetes mellitus had a congenitally small pancreas since all gourmands did not develop diabetes mellitus.

The second group consisted of patients in whom acute diabetes had developed comparatively recently. Occasionally the onset was associated with some definite disease, or with a slight pyrexia suggestive of an infective origin. Dr. Leyton had seen quite a number of young people who had given similar histories—namely, that they had felt feverish, had been sent to bed for a few days by their doctor, and had attributed their thirst to the fever, but that after getting up the thirst had persisted. This had led to an examination of the urine which demonstrated sugar.

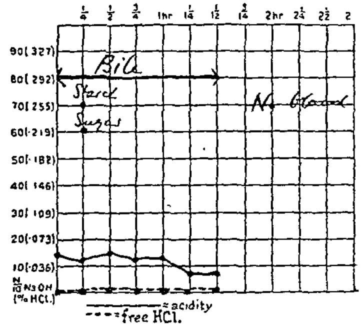
The third group consisted of all those cases in which the pancreas had deteriorated to such an extent that it was impossible to find a diet possessing sufficient energy to maintain life and keep the blood-sugar normal. This group contained the patients who earlier

FIG. 8.



M. W., aged 39 (16/10/1920): Carcinoma pylorus. Note presence of blood and low degree of free acid.

FIG. 9.



Same patient as Fig. 8 (15/1/1921): After gastro-jejunostomy and partial gastrectomy. Note diminished total acidity and free acid; bile present throughout. Absence of blood in second meal.

ulcers (simple or with stenosis); (3) duodenal ulcers. Growths form a fourth group, regardless of type of operation.

(b) No matter the type of operation (e.g., gastro-jejunostomy alone or together with excision of the ulcer), in prepyloric ulcers the curves obtained before and after operation differ in that the free hydrochloric acid is diminished, but the total acidity reaches roughly its previous level; bile enters the stomach during the meal, and the stomach is emptying more rapidly than before.

(c) Pyloric ulcers, after gastro-jejunostomy, have the same type of curve as before operation.

(d) Duodenal ulcers have a highly acid resting juice, with a slightly diminished free hydrochloric acid, and the remaining part of the curve reaches about the same maximum as before, although it may be obtained quicker after operation.

(e) Carcinomata have a low free and total acidity both before and after gastro-jejunostomy.

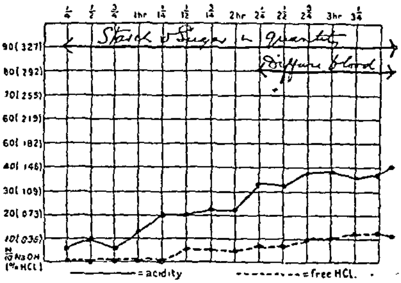
(f) In all cases of gastro-jejunostomy the stomach is emptying quicker than before the operation.

(g) In all cases a varying amount of bile gets into the stomach during some part of the meal.

(h) In all cases when the gastro-jejunostomy has been successful, pain has been relieved.

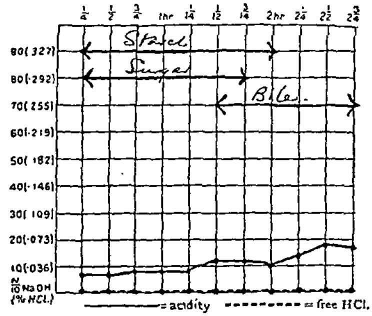
(k) In most cases of simple ulcer weight has been put on.

FIG. 10.



A. C., aged 51 (9/1/1921): Carcinoma ventriculi. Note great delay in emptying of stomach. Low free acid; presence of blood.

FIG. 11.



Same patient as Fig. 10 (27/6/1921) after gastro-jejunostomy. Note presence of bile; no visible blood; stomach emptying more quickly than before. No free acid in second meal.

I should like to take this opportunity of expressing my thanks to the surgeons and assistant surgeons of Guy's Hospital for the facilities they have given me to make use of their cases, and particularly to Dr. Ryffel and Dr. Ryle for numerous suggestions and advice on the varying difficulties that had to be overcome.

GENEVA MEDICAL SOCIETY.—Dr. F. G. Crookshank will deliver the Revilliod-Julliard Lecture on Thursday, Nov. 10th, the subject being the Traditions and Development of British Medicine.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—The first meeting of the session was held at the Miller Hospital, Greenwich, on Oct. 14th. Dr. C. T. T. Comber was elected President and on taking office remarked that the society was the oldest local medical society in the London area, being instituted in October, 1856. Mr. Cecil A. Joll showed a female patient of 79 years of age from whom he had removed part of the stomach. Dr. H. Nockolds showed a curious case of generally distributed and painful bony tumours which had been present from birth. Dr. Montague Hine showed two cases of glaucoma, a case of complete ophthalmoplegia externa, and an injury to the retina due to a shrapnel wound of the cheek. Mr. Hugh Davies showed part of the stomach removed from a woman aged 75 years very similar to the case of Mr. Joll. Dr. E. P. Cumberbatch showed a case from whom he had removed a bony growth from the heel by caustic potash and ionisation.

out of the diet in the home depended, as a rule, upon the patient, who should know the why and wherefore of each step and be able to make simple changes for himself. Dr. Spriggs had recently introduced at Duff House a short course of instruction for patients while their cases were being investigated. A class was held by the diet sister, in which patients were shown how to weigh certain portions of food accurately and how to make special dishes, including diabetic bread. In the chemical laboratory instruction was given in the collecting and measuring of urine, and, in certain cases, its testing. The scheme included also simple instruction by a doctor in the nature of food and food-stuffs, food values, the reasons for the dietetic measures adopted in diabetes, and the construction of the patient's own diet. A selection was made of the patients who would be invited to attend the course or any part of it. In the young, with well-marked diabetes, anxiety and apprehension might be engendered, but the judicious instruction of patients about diet need not make them as apprehensive as they used to be in former days on a diet of abundant protein and fat, on which glycosuria and symptoms were increasing. The time for which a serious breakdown of metabolism could now be postponed in young patients was still unknown, but it was certainly several years longer than formerly. While laying stress on the value of keeping the urine free from sugar it was important not to give the patient the impression that all was lost if this result could not be attained, since experience showed that many people who could not be kept free from sugar could live and work.

With older patients and less severe types the closest collaboration of the patient and the fullest knowledge of the modes in which the proportions of protein, carbohydrate, and fat can be varied in the diet were wholly advantageous. In such the control of his own diet by the instructed patient might postpone indefinitely the progress of the complaint. Dr. Spriggs was of opinion that every hospital should have a course of instruction for both in- and out-patients with diabetes. The expense would be trifling, and the benefit to the sufferers would be great.

Home-made Diabetic Bread.

Every doctor was aware that most of the diabetic breads offered to the public, with the exception of those made by one or two well-known firms, either contained a great deal of starch and sugar, or were unpleasant to the taste, whilst all were expensive. Messrs. Callard and the Protene Company had made products which gave fairly consistent analyses, and these were used widely. Patients were well advised to do without bread or bread substitutes altogether, eating boiled greens with meat, and lettuce or tomatoes, &c., with eggs. But the need for a bread substitute remained. A particular disadvantage, even of the reliable breads, was that they contained a good deal of fat. When the diet was being built up after fasting it was convenient to have a bread substitute which did not contain fat. After a careful trial of bran cakes, which were not found, even with the same method of preparation, to be consistently starch-free, he had suggested to the chemist and the diet sister at Duff House that fat-free casein bread should be prepared from separated milk. The method at present in use was as follows:—

Duff House Home-made Diabetic Bread.—One gallon of separated milk (cost about 6*d.*) is placed in an enamel dish and warmed, with stirring, to 100° F. A mixture of 45 c.cm. (= 1½ fluid oz.) of glacial acetic acid and 450 c.cm. water (about ¾ pint) is prepared and poured into the milk at 100° F., with constant stirring. The caseinogen separates as a white clot. The mixture is left to stand for about five minutes and then poured through muslin placed on a fine sieve for about two minutes, meanwhile working the caseinogen with the hand so that most of the other milk products and acid may be washed away. The muslin containing the precipitate is taken from the sieve, pressed, placed in a bowl of cold water, and kneaded for about five minutes. The water is now changed six times with repeated kneadings each to ensure that all traces of milk-sugar are removed from the casein. The washings are to be tested with Fehling's solution. The muslin containing the white material, henceforth called "casein," is squeezed to remove as much liquid as possible, the muslin opened out, placed on a sieve, and left on the kitchen shelf for a few hours to dry. The casein is now rubbed through the sieve on to the muslin and put back on to the shelf overnight or until it is practically dry to the touch. About 160 g. (5½ oz.) of the casein in this condition should be obtained from one gallon of separated milk.

To prepare the bread beat up the whites of two eggs to a stiff froth, add 50 g. of the above casein (nearly 2 oz.), a pinch of salt, and 2 g. each of cream of tartar and bicarbonate of soda (i.e., a teaspoonful of each powder, levelled off, but not pressed down). Mix lightly together, form into cake or cakes and bake in a moderate hot oven for 15 to 20 minutes. The tin on which the bread is baked should be greased with liquid paraffin. This gives an unpleasant smell in the oven, but the bread has no taste of it.

The casein can be prepared at any time and in any quantity at the convenience of the housewife. It is best kept in a dry place in open vessels. The bread itself is made in a few minutes by whipping up the casein with the egg white, salt, and baking powder. Sweet cakes can easily be made from it by putting in a little liquid saccharin and some desiccated cocoanut or other flavouring. When freshly baked the well-known and objectionable cheesy taste of diabetic bread is less marked in this bread than in those on the market, but it is important that it should be made and eaten fresh; this taste develops if the bread is kept long. As the making and baking take only a very short time, it is easy by keeping a supply of casein powder to make bread fresh once a day or more than once a day.

The analysis of the bread as served gave: Protein (nitrogen × 6·25), 52·5 per cent.; carbohydrate (starch and sugar), nil; fat (ether extract), 0·2 per cent.; 20 g. of it gave, therefore, approximately 10 g. of protein. In addition to its general use as a not unpleasant and inexpensive home-made bread substitute, rolls of about 20 g. are specially valuable when it is desired to increase the protein daily after fasting, without adding fat or carbohydrate.

Dr. Spriggs said that with eggs at 3*s.* 9*d.* a dozen the cost worked out at a little under 3*d.* for each 20 g. roll. The yolks of the eggs were, of course, included in the price, but would be used for some other purpose, such as for custard. Dr. Spriggs showed actual rolls, and also some small cakes made from the same material and flavoured with coconut.

The Treatment of Coma.

Dr. E. P. Poulton said that he agreed with the previous speakers as to the general treatment of diabetes, but wished to say something about the treatment of coma. He described a case of a comatose child of 9 whose alveolar CO_2 amounted to only 1·5 per cent.; Dr. Poulton injected intravenously 300 c.cm. of a 5 per cent. solution of sodium bicarbonate, followed by rectal dextrose, lactose by the mouth, and later by subcutaneous saline. The alveolar CO_2 rose to 5·2 per cent. on the nineteenth day. The patient was finally discharged from hospital on a diet sufficient to maintain and even to increase the weight. Dr. Poulton described the administration of saline through a tube passed into the duodenum to another patient and expressed his conviction that the introduction of saline was of definite service in diabetic coma.

Treatments Compared.

Dr. George Graham agreed with Dr. Spriggs that it was most important to teach the patient a great deal about his disease in order that he might understand the details of its treatment. After the patients left hospital, it was often impossible for them to collect their urine during the whole of the 24 hours, and the patient should test the urine which was passed after the principal meal of the day. The difference between Allen's line of treatment and that used in St. Bartholomew's Hospital was not very great. The same principle of undernutrition was maintained, but whereas Allen started the diet by adding carbohydrates in the form of vegetables, at St. Bartholomew's the carbohydrate value of the diet was kept as low as possible, while the proteins and fats were increased. Allen's recent work on dogs had shown that it was much easier to convert a mild diabetic dog into a severe diabetic one by overfeeding with sugar than with starch. It was cutaneous nodules, especially on the right upper arm, which appeared, according to the patient, about seven months before. Before coming here the eyes were examined by Captain P. J. Hay, R.A.M.C., who reported as follows: Two local detachments of the retina of right eye due to cyst-like bodies behind; deficient vision in left eye, apparently due to opacities in the lens; fundus normal. No ova of parasites could be found in the stools, and the urine was normal. The Wassermann reaction was negative and the blood count showed only slight lymphocytosis. One of the small cysts was excised from the right arm and sent to the London School of Tropical Medicine and reported to be *Cysticercus cellulosæ*, and the opinion was expressed that she must have been both the direct and intermediate host of this parasite. There had been no sign of the intestinal infection while in hospital. She improved gradually in mental and bodily condition and was discharged recovered in December, 1918. She was readmitted on July 18th, 1919, again suffering from melancholia, and was said to have been upset by the sudden death of her husband. Early in 1921 she developed tuberculosis. The disease made rapid progress and she died on Sept. 14th.

Post mortem it was found that the whole convex surface of the brain was studded with cysts, as was also the heart. Neither organ was opened, as I wished to send them to the museum of Trinity College, Dublin. The subcutaneous tissue of arms, thorax, and abdomen was full of cysts, and the peritoneum was profusely studded with them. There were none in the lungs, liver, kidneys, or spleen, but the lungs were full of tubercle.

A CASE OF ACUTE TETANUS,

SUCCESSFULLY TREATED WITH LARGE DOSES OF ANTITETANIC SERUM.

BY C. E. SHATTOCK, M.S. LOND., F.R.C.S. ENG.

THE following case of acute tetanus, successfully treated with large doses of antitetanic serum (A.T.S.) would seem worth recording, as showing the large quantity of A.T.S. which may be safely given in early childhood.

F. L., aged 3½ years, injured the tip of one finger in a street accident. She was noticed not to be well and to stumble when walking 11 days after the accident. On the twelfth day she could not get food into her mouth, and in the evening "fits" began, the child becoming stiff whenever she was touched. One thousand units of A.T.S. were given subcutaneously by her doctor on the thirteenth day, and a further 1500 units subcutaneously early on the fourteenth day. When the patient came under my care (Sept. 29th, 1920), the fourteenth day after the injury, she showed generalised rigidity, most severe in the arms; there were marked trismus and some opisthotonos. The facial muscles showed tremors, the reflexes were increased, and the child was sweating profusely. Pulse 148, respiration 36, temperature 100·4°. There was a sloughing wound on the tip of the injured finger. A.T.S. was administered as shown in the table:—

Date in 1920.	Intravenously.	Intramuscularly (each injection, 750 units).	Subcutaneously.
28.9	—	—	1000 units.
29.9	4500 units.	3 injections.	1500 ,,
30.9	4500 ,,	4 ,,	—
1.10	—	5 ,,	—
2.10	—	4 ,,	—
3.10	—	3 ,,	—
4.10	—	2 ,,	750 units.
5.10	—	—	750 ,,

The patient was anæsthetised for the intravenous injections, the serum being diluted with saline; the terminal phalanx of the injured finger was amputated whilst the first of these injections was given, the wound being left open and subsequently dressed frequently with H_2O_2. Chloral, gr. v., with pot. brom., gr. x., was administered two-hourly during Sept. 29th and 30th, and was then continued in the same dosage four-hourly until Oct. 11th.

The patient's general condition improved greatly during the first 48 hours of treatment, but the general rigidity passed off slowly, being quite noticeable on Oct. 7th. The jaw was still slightly stiff on the 12th. On the 19th the child seemed perfectly well. The total number of units of antitetanic serum given to this child was: intravenously, 9000; intramuscularly, 15,750; subcutaneously, 4000.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

A MEETING of this society was held on Oct. 24th, Mr. JAMES BERRY, the President, being in the chair, when Sir ARCHIBALD GARROD opened a discussion on

THE MODERN TREATMENT OF DIABETES.

He called attention to the advances made, in recent years, in the study of diabetes and allied conditions; the estimation of sugar in the blood, as well as in the urine, had thrown much light upon the metabolic disturbances, and had given valuable indications for prognosis and treatment. Such estimations, for which only minute quantities of blood were required, enabled us to distinguish between cases in which the blood-sugar was high, normal, or subnormal, and to study the response to the administration of doses of glucose. We were learning that the prognosis of diabetes was not so uniformly gloomy as was formerly thought, and that there were cases to which the name of diabetes innocens might rightly be applied. The "threshold," by which was meant the degree of glycæmia above which sugar begins to appear in the urine, was a matter of interest and importance, and there were indications that the patient might protect himself, to some extent, by a raising of this threshold. Sir Archibald Garrod said that it had been recognised for some long time that the tolerance of the patient for carbohydrates became impaired progressively as the disease continued, and that by dietetic restraints it was possible to bring about some recovery of tolerance, with the result that after a period of "alimentary rest" the patient could take larger quantities of carbohydrate food without passing sugar in his urine. Of recent years much attention had been directed to the part played by the substances of the acetone group, and especially by aceto-acetic acid, in diabetes, and in the production of diabetic coma. We had learnt much as to the sources of these products in the body, and the influence of restrictions of diet upon their production. The prime objects aimed at in the dietetic treatment of diabetes were the reduction of the amount of sugar in the blood, and the consequent resting of the damaged mechanism, and at the same time the avoidance of over-production of the acetone bodies. Sir Archibald Garrod sketched the progress of dietetic treatment from its inception by Rollo in the early part of the nineteenth century, through the period during which the elimination of carbohydrate from the diet was the chief aim; he recalled the gradual improvement of that method and the recognition of the danger of too abrupt or rapid restrictions. He alluded to the Guelpas plan of treatment by fasting days and copious purgation, to the oatmeal treatment of von Noorden, and lastly to the most modern plans of treatment introduced by Allen in America, and by Graham in this country. These two plans of treatment were reached independently along different lines: both relied largely upon fasting days, and both produced results far better than had been obtained on any previous plans. Timidity in imposing fasting days, on the ground that starvation induced acetonæmia, has proved to be unjustified; far from increasing acetonæmia, fasting days tended to diminish or remove it. Sir Archibald Garrod described the modern treatment of diabetes as based upon the value of periods of alimentary rest in restoring carbohydrate tolerance; i.e., on the facts which Allen had brought out clearly, that a diabetic patient did best when somewhat underfed, and that restriction of protein and fat was no less important than restriction of carbohydrates. Patients treated by modern methods seldom passed sugar in their urine, and in hospitals it was often difficult nowadays to find specimens of sugary recognised in the skiagram: but without stereoscopic pictures the interpretation was not always correct. A mastoid process with pneumatic spaces occurred in 79 per cent. of European skulls. In the 1000 crania, anatomical asymmetry occurred in 12 per cent., mostly that of a pneumatic process on one side, an infantile on the other. Clinical asymmetry—i.e., as contrasted with anatomical—obtained in only 7 per cent. of the skulls. In Esquimaux, Melanesian, and Polynesian crania the pneumatic processes were found greatly to preponderate, irrespective of the type of skull. The frontal sinus, like the pneumatic mastoid process, was oftenest found in the brachycephalic skull. The frontal sinuses were better represented in the crania of the mixed European peoples than in the skulls of the relatively pure races, the pneumatic mastoid processes being found chiefly in relatively pure breeds of men. There was no evidence that the frontal sinuses and the pneumatic mastoid spaces attained a similar degree of development.

Mr. ARTHUR CHEATLE alluded to the remarkably close percentages to Dr. Turner's figures which he himself arrived at by the examination of a large series of skulls.

Diagnostic Exploration of Posterior Ethmoidal Cells.

Mr. E. WATSON-WILLIAMS read a paper by himself and Dr. P. WATSON-WILLIAMS (his father) on this subject. The cells are entered with a cannula similar to that used for the sphenoidal sinus. It is passed into the nose, above or below the middle turbinate, until it rests on a point corresponding to the back of the middle turbinate in its attachment. The cell can then be washed out and the contents examined. Unless the entry is found to be easy, the attempt should not be persisted in, for pressure brings risk of disaster. To do the exploration the nose should be pushed over to the opposite side.

Vertigo Cured by Ossiculectomy.

Sir J. DUNDAS-GRANT showed a woman, aged 40, who had had attacks of vertigo with loss of consciousness and occasional double vision two or three times a month for a number of years. Sometimes she lost the vision of the right eye for about two minutes, also she had attacks of double vision. Pus had been periodically discharged from the ear since childhood. A large perforation in the attic was found, through which desquamative material protruded. After ossiculectomy she had been free from pain, and there remained only a slight "swimminess."

Result of Double Schwartze Operation.

Mr. L. COLLEDGE showed a female child, aged 6, on whom, last December, he did a Schwartze operation on the left mastoid for acute suppuration; and three days later the same was done on the right ear. In both ears the tympanic membrane had now healed, and all suppuration had ceased; a large dry cavity still persists in the left mastoid, though both sides were treated alike.

SECTION OF PATHOLOGY.

A MEETING of this section of the Royal Society of Medicine was held on Oct. 18th with Dr. W. S. LAZARUS-BARLOW, the President, in the chair.

Dr. J. C. MOTTRAM read a paper on

Observations Upon the Action of Radium and X Rays Upon the Mononuclear Leucocytes of the Blood.

He said that by direct measurements of the size of mononuclear cell in the blood of rats he had found that in the lymphopænia following radiation the small lymphocytes were greatly diminished whilst the larger types remained relatively unaltered in numbers. This finding could account for the facts discovered by Prof. Russ and his collaborators, that the percentage decrease in lymphocytes following X radiation is more or less constant over a wide range of dosage, and that a second exposure to radiation, before regeneration has occurred, does not cause a further in the number of circulating lymphocytes.

Dr. W. CRAMER and Dr. MOTTRAM contributed a paper on Changes in Lymphoid Tissue after Exposure to X Rays, and in Vitamin Starved Animals.

Dr. J. A. MURRAY demonstrated sections illustrating the Dissemination along Nerve Trunks in Tar-cancer.

Prof. S. G. SHATTOCK showed a section demonstrating Dissemination along Nerve in Carcinoma of the Tongue.

Dr. A. LEITCH showed Casts of Tar-tumours in Rabbits.

Dr. C. C. OKELL read a paper on the

Sachs-Georgi Reaction in Syphilis,

the purpose of which was to give the results of a number of tests by two modifications of the original reaction. In the first method the antigen used was prepared by mixing five parts of a simple alcoholic extract with five parts of a 1 per cent. solution of cholesterol in alcohol. This was diluted with an equal quantity of saline run slowly down the side of the tube, and the tube was then shaken. More saline was then added to make a dilution of 1 in 10; the resulting fluid was a suspension of cholesterol protected by the presence of the lipoidal extract. It had a shimmering watered-silk appearance. The serum was inactivated and tubes containing 1 c.cm. of dilutions 1/10, 1/20, 1/40, 1/80, were put up. To each tube 0·5 c.cm. of antigen dilution was added; the tubes were shaken and incubated at 37° C. Readings were taken over-night and in 48 hours. Definite flocculation in any of the tubes was read as a positive reaction. Controls were, of course, included. The results of 550 tests compared with the Wassermann test were as follows:—

Total	..	S.G. + W.R. +	S.G. − W.R. −	S.G. + W.R. −	S.G. − W.R. +
550		138	357	7	48

Total agreement 90 per cent.

The special points in favour of using an antigen rich in cholesterol were: (1) flocculation being heavy the tests were usually simple to read; (2) the reaction was usually well-marked, even in turbid or blood-stained sera or sera preserved for several months with chloroform; (3) only 1·27 per cent. of cases gave a positive Sachs-Georgi reaction and negative Wassermann reaction, so that where the Sachs-Georgi was used in place of the Wassermann only a small percentage of patients would be unnecessarily submitted to treatment.

The second method employed was the Dreyer-Ward[1] modification. Dr. Okell said that the features of this modification were: (1) The serum dilutions start low 1/1·25 or 1/2·5, and go up to 1/462; (2) the lipoidal extract is prepared by Bordet's method and appears to be very constant—the cholesterol content is low; (3) the standardisation of apparatus and methods, the whole technique being similar to Dreyer's standard agglutination methods; (4) the ease with which flocculation can be read against the controls which are opalescent in appearance but free from visible particles; (5) the test is claimed to be particularly useful for following the results of treatment; and (6) high percentage of agreement with the Wassermann reactions. The disadvantages were: (1) The reaction is somewhat more difficult to carry out than the original Sachs-Georgi reaction; (2) more serum is required; (3) the serum should be free from contamination or turbidity and must not contain preservative; and (4) seven hours incubation in a water bath at 37° C. are sometimes difficult to fit in with the ordinary laboratory routine. Dr. Okell said he had found that all the small technical details accentuated by Dreyer and Ward must be carefully observed if good results were to be obtained. His results were:—

Total	..	S.G. + W.R. +	S.G. − W.R. −	S.G. + W.R. −	S.G. − W.R. +

might have belonged to group 1 or 2 and in whom the disease had been neglected or treated incorrectly; but in addition to these cases, in some patients the disease was progressive in spite of the most skilled modern treatment, possibly due to a chronic infection of the pancreas. Apparently chronic infection was not essential, for in many cases in which the alteration in the pancreas seemed to have been arrested, toxin resulting from an incidental infection such as tuberculosis, influenza, or malaria, might cause progress in the disease.

Appropriate Restricted Diet.

Dr. Leyton said that the treatment of these three groups might be termed a treatment of restricted diet. Restricted diet by itself was sufficient in group 1. Usually these patients had a blood-sugar in the region of 0·2 per cent. about two hours after a meal containing carbohydrate, but no evidence of an acidosis. In these cases the blood-sugar fell to normal upon restricting the daily diet to: carbohydrate 20 g., protein 50 g., fat 50 g. When this diet had been taken for seven days and the blood-sugar had fallen to normal, a daily increase in the carbohydrate was made and the blood-sugar was estimated at intervals. Directly the blood-sugar began to rise above the normal the quantity of carbohydrate was reduced. Protein might then be raised perhaps up to 2 g. of protein per kilo body-weight, provided the blood-sugar did not rise; and then, finally, fat might be increased until the number of calories per kilo per diem became 30, or the blood-sugar rose or some evidence of acidosis developed. The treatment of the second group was much less easy; the removal of sugar from the urine was simple, but the elaboration of a diet which would arrest the progress of disease in the diabetic and allow the patient to live indefinitely was far from simple.

Most important was the eradication of any infection. Recently attention had been drawn to a condition called "sapræmic glycosuria." Assuming that such a condition existed, Dr. Leyton pointed out that to treat true diabetes mellitus in association with a sapræmic glycosuria would be beyond the skill of any man with the present methods of investigation, for in sapræmic glycosuria the sugar in the blood and the sugar in the urine was increased. Pyorrhœa alveolaris, pustules, and infected tonsils all led to an alteration in metabolism which made the estimation of the optimum diet impossible. Dr. Leyton quoted cases in support of his contention that infection affected the metabolism and that the amount of toxin necessary to change the metabolism was minute. The ideal diet for the diabetic was one in which sufficient energy was supplied in the food whilst the sugar in the blood did not rise above 0·12 per cent. and no excess of any acid or acetone appeared in the urine. In the more severe cases of diabetes mellitus this ideal diet could only rarely be attained, although frequently a diet could be found in which glycosuria was absent, while the blood-sugar rose to 0·18 per cent. Dr. Leyton's experience showed that in these cases the disease was progressive, and therefore the problem resolved itself into the decision how far the patient should be submitted to the inconvenience of a very limited diet in order to prolong life for some months or perhaps years. In some cases a patient would not submit to any very great restriction without a reasoned argument. The opportunity of discussion with the patient should be afforded to the consultants in such cases. Dr. Leyton said that in a certain number of cases belonging to group 3 the patient's urine could not be freed from sugar. The majority of these cases were either very advanced, or were suffering from pulmonary tuberculosis. By giving large doses of atropine and codeine sugar might sometimes be expelled from the urine, but it had not been his custom to use this method. In Dr. Leyton's opinion, when it became evident that life could not be prolonged indefinitely, the object of treatment was completely changed; a diet had then to be arranged whereby the patient would get the most satisfaction out of the remainder of his life.

The Importance of the Blood-sugar Curve.

Dr. W. LANGDON BROWN said that true diabetes was characterised by an exaggerated katabolism involving all the foodstuffs. Since carbohydrate formed about 70 per cent. of the normal diet and yet was not present in the tissues to more than 1 per cent. of the body-weight, it was clearly the most rapidly metabolised food; hence it would be the first affected in exaggerated katabolism. Dr. Langdon Brown brought forward observations to show that carbohydrate tolerance varies with the total metabolism. The success of treatment by alimentary rest depended on the way that it could slow down the whole of the metabolism. The special point to which he wished to call attention was the guidance that can be obtained in treatment by investigation of the blood-sugar curve in glycosuria. It had generally been assumed that hyperglycæmia preceded glycosuria, but by following up the course of a case it might often be seen that in the earlier stages hyperglycæmia was slight and transitory, becoming much more marked later on, showing that the kidney was capable of raising its threshold for sugar. Dr. Langdon Brown showed a number of curves illustrating (1) the normal response of the body to the ingestion of sugar; (2) cases with a low threshold, the so-called renal type, which required no treatment; (3) cases of obesity with consecutive glycosuria, showing an impaired power of storing sugar as glycogen; (4) cases of exophthalmic goitre, showing marked delay in dealing with ingested sugar, with consequent hyperglycæmia but not necessarily any glycosuria; (5) cases of transitory or intermittent glycosuria where the sugar curve showed a short, sharp rise above the threshold, but a normal fall. For this type he did not advise abstention from starch, usually abstention from sugar as such was sufficient. The next series of curves, (6), showed mild and intermittent forms of the disease, some of which were suitable for treatment by alimentary rest, while others did better with more lenient methods. The final group, (7), were cases of severe diabetes, practically all showing continuous hyperglycæmia with an extraordinarily sharp rise and then fall after administration of dextrose. In all these alimentary rest seemed strongly indicated, and Dr. Langdon Brown quoted instances of the good effect of this treatment. In two cases he had observed the threshold for sugar pushed up so much that the blood held a considerable quantity of sugar and only a small amount escaped into the urine in a manner recalling the renal type, since it varied little with the diet. The blood-sugar curve was, therefore, necessary to distinguish a case of this sort which required active treatment from one of the renal type where no treatment was called for. After experience of both Allen and Graham's methods of treatment by alimentary rest, he had come to the conclusion that although Allen's plan might rid the urine of sugar more quickly it was more trying to the patient than Graham's, and the ultimate results of the latter appeared to him as good.

The Education of the Patient.

Dr. E. I. SPRIGGS said that the fasting treatment in diabetes had been used at Duff House for six years. The first 18 months' experience of the method was described in a discussion at the Royal Society of Medicine in May, 1916.[1] Subsequent work had confirmed the good report of the method then given. Dr. Spriggs wished to speak on two points—first, the importance of the education of the patient so that he could coöperate with his doctor in the treatment, and, secondly, on the home-made manufacture of a starch- and fat-free bread substitute. The preliminary examination of the case should be made under medical care, with daily examinations of the urine, frequent blood-sugar estimations, and a weighed diet. On the results of this investigation, which might take from a fortnight to six weeks, a scheme of diet should be drawn up. The carrying

PATHOLOGY.

A Text-book of Special Pathology. Second edition. By J. MARTIN BEATTIE. M.A.. M.D., Professor of Bacteriology. University of Liverpool; and W. E. CARNEGIE DICKSON. M.D., B.Sc.. Director of the Pathological Department. Royal Hospital for Diseases of the Chest, London. London: William Heinemann. 1921. Pp. 591. 31*s.* 6*d.*

THIS is the companion volume to the authors' "Text-book of General Pathology" which was reviewed in THE LANCET of July 30th. but whereas in the first edition it had a separate existence, it is now quite definitely Part II., for the numbering of the pages and figures is carried on from the first volume. There has been little progress in morbid anatomy in the last few years, but the authors have revised their book and considerably enlarged it, and the opportunity has been taken to notice recent work on such subjects as heart-block, dysentery, and gastric ulcer. In other branches, however, the teaching is somewhat old-fashioned—the treatment of cirrhosis of the liver, hypernephroma, and myeloma leaves a good deal to be desired; while the chapters on Bright's disease and arterio-sclerosis are neither very clear nor very profound. A curious omission in a work of this magnitude and price is that of the description of the pathology of the female genital organs. It is undoubtedly true that this branch of the subject is dealt with in text-books of gynæcology; but it is also true that a certain amount of pathology is included in practically every general or special text-book on medicine or surgery. It is the province of the pathologist to consider disease processes from a different—possibly a broader—point of view than the physician or the surgeon, and this voluntary abdication of the position is scarcely to be commended. Several new illustrations, some very good, have been introduced, but on the whole the illustrations are not the most satisfactory feature of this work, which is for the rest admirably suited to the needs of the student.

General Pathology: An Introduction to the Study of Medicine. Being a Discussion of the Development and Nature of Processes of Disease. By HORST OERTEL. Strathcona Professor of Pathology and Director of the Pathological Museum and Laboratories of McGill University and of the Royal Victoria Hospital, Montreal, Canada. New York: Paul B. Hoeber. 1921. Pp. 357. $5.
